THE POINT OF ELECTION AND MODES OF INVASION IN PULMONARY TUBERCULOSIS

J. O. COBB, M.D.
Surgeon, U. S. Public Health Service
CHICAGO

In this review of the modes of invasion in pulmonary tuberculosis, all minor avenues of entrance of the bacillus have been disregarded, and only inhalation and ingestive methods will be considered.

It is generally accepted by pathologists that the first stage of pulmonary tuberculosis is an involvement of the glandular and lymphatic structures of the lungs. Postmortem and roentgenographic evidence seems to prove that tuberculous foci are not established in lung tissue proper until after the peribronchial glands have been seriously damaged by the invading organisms. This is the so-called pretuberculous stage of the disease. In hundreds of reported necropsies, especially of children, foci in the peribronchial glands were the only demonstrable lesions in the body. This analogy has also been reported in comparative pathology, especially in cattle, which have been more carefully examined than other animals. In pseudotuberculosis of sheep and cattle, the pulmonary glands are first involved. Pulmonary pigmentation in man and animals shows first in the peribronchial glands. This view of the matter is strengthened further by the observation of human and veterinarian pathologists that if a focus is found in the lung tissue proper, this lesion is invariably accompanied by involvement of the pulmonary glands.

If the dosage is maintained, and other conditions are favorable, crippling of the peribronchial glands is followed by the arrest of a bacillus and the formation of a tubercle in lung tissue proper; and if this focus progresses to softening, it breaks through into the air vesicles, or into adjacent healthy tissue, where, in the latter case, bacilli that have been set free are again arrested by the highly complex system of lymph channels and glandular locks. In many cases, experts in roentgen diagnosis are now able to demonstrate involvement in the peribronchial glands, especially in children, long before the appearance of cough and sputum, thus furnishing the clinician ample grounds for the long entertained belief that cough and expectoration are secondary and late manifestations of pulmonary tuberculosis.

The problem, then, is to analyze the common anatomic methods, or routes, by which tubercle bacilli reach the point in lung tissue where they are arrested and colonized.

THE POSSIBILITY OF FOREIGN MATTER BEING INHALED DIRECTLY INTO THE AIR VESICLES

Minute particles of carbon, stone and such dust reach lung tissue, but the deposit of foreign matter in the interalveolar tissue or the lymphatic channels or the pulmonary glands does not prove that it was carried there in the ordinary process of respiration, as this function is commonly understood.

The general belief that anthracosis is due to the direct inhalation of dust is based largely on the fact that in miners and firemen, and certain stone cutters, the deposits of gritty matter can be demonstrated macroscopically as well as microscopically. This view of the question was seemingly upheld by Rindfleisch, who was able, in a series of necropsy studies of the lungs of charcoal workers, to demonstrate, and actually to classify, the carbonized wood deposits in the microscopic sections of the pulmonary tissues and in the peribronchial glands.

Nevertheless, if the histology of the respiratory mucous membrane is kept in mind, one cannot escape the conviction that the tidal air in its excursions up and down the trachea and bronchia would undoubtedly impinge foreign bodies somewhere on the long stretch of ciliated mucous membrane. One step further, by granting such a probability, establishes a profound doubt in one's mind whether dust or bacteria are ever actually driven directly into the air sacs in the ordinary act of breathing, or even by forcible inspiration.

And yet, pneumococci, influenza bacilli and other bacteria actually reach and grow in the air vesicles. The speculation that phagocytes might carry these organisms direct to the air sacs and plant them there has been offered as a solution of this perplexity, but it is a more reasonable explanation that these organisms, gaining a foothold on the bronchial mucous membrane, finally reach the air vesicles by an extension of the colony growth. Many writers believe that phagocytes pick up coal dust on the bronchial mucous membrane and carry it into the air sacs, and thence into the pulmonary lymph stream; but this seems improbable, if it is considered that even though the wandering cells do pick up dust and bacteria on the bronchial mucous membrane, these cells surely would be wafted along by the cilia, and finally driven out through the trachea, just as coal dust is driven out.

Many careful sections have been made of specimens from the lungs of miners accidentally killed while at work, and though the bronchia were markedly filled with coal dust, it was difficult for these investigators to demonstrate to their entire satisfaction any foreign matter in the air sacs themselves, notwithstanding the fact that the interlobular spaces and lymph channels were filled with carbon deposits

However, there is a histologic peculiarity of the deeper portion of the respiratory mucous membrane that must not be overlooked in this connection. The minute, terminal branches of the bronchioles are not supplied with cilia, and if bacteria or dust got past the cilia and reached this deeper portion of the bronchia. undoubtedly the suction or pull of the adjacent lymph streams would draw them backward into the air sacs, and thence into open lymph vessels, in which they would drift until arrested in some glandular storehouse along that chain.

Piersol says:

> Between the air vesicles, minute openings or stomata exist; they usually connect with microscopic passages leading into the lymphatic channels. By means of these channels, particles of inhaled foreign matter, often deeply pigmented, are carried from the air sacs into the lymphatics, and become lodged within the interlobular connective tissues.

Cornet presented to the medical world a mass of experimental evidence in proof of the inhalation method of infection of the lungs. Fluegge demonstrated that fine droplets of sputum were driven to considerable distances by consumptives in the act of coughing or sneezing. Hoffman infected guinea-pigs by means of a spray of tuberculous sputum. Buchner and Enderlein succeeded in infecting small animals without the spray, merely by exposing them in the room to droplets of sprayed sputum. The ordinary inhalation method was used by Nocard, Rossignol and Kossel to infect calves, by Reichenbach to infect goats, and by Tappeiner to infect dogs.

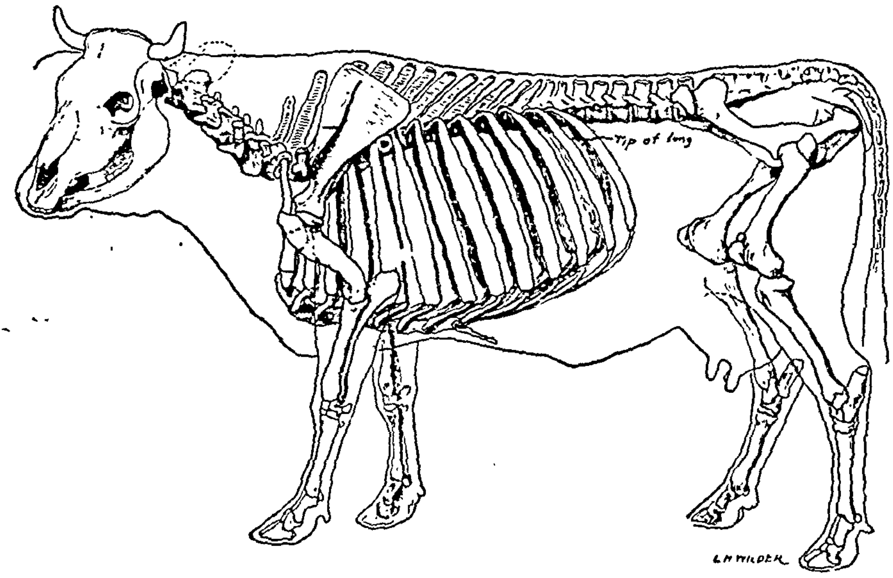

Fig. 1.—Skeleton of cow. Arrow points to location of tip of lung, which is the point of election in bovines. From Sissons.

Guerin and Grysez raised the issue that the possibility of swallowing had not been eliminated in these experiments, but the objection was immediately countered by Fluegge, Bartel and Neumann, using guinea-pigs, and by Titze and Weber, using calves, all of whom demonstrated that within a few minutes after exposure to infected dust, every portion of the lung showed the presence of tubercle bacilli, while the control exposure by feeding was much slower. Findel, working with guinea-pigs, used graduated dosage in the two methods, and found that it required only a fractional dose to infect by inhalation; while in the control animals it required a hundred times greater dosage to infect by ingestion. Titze and Weber, working with calves, demonstrated that the average dose required to infect the animal by inhalation was 0.01 mg., while it required 10 mg. of the same culture to infect by feeding.

Not satisfied with these experiments, which were still open to objection, Findel opened the trachea of dogs and calves and produced pulmonary infection by direct inhalation of tubercle bacilli. This particular experiment has been confirmed by a number of investigators. Similar inhalation experiments with the *Bacillus prodigiosus* were made by Hartman and Hartl, with mold fungi by Hilderbrand and Ballin, and with India ink by Kuss, for the purpose of demonstrating that these organisms and the ink could enter the lung tissue as foreign bodies by way of the respiratory mucous membrane.

Arnold and Penfick went a step further by attempting to produce experimental anthracosis by means of inhalation, but Grysez and others could not confirm Arnold's and Penfick's work, and they concluded that anthracosis was a condition that was induced by swallowing dust, the carbon reaching the lungs by way of the intestinal tract.

Finally, because of the constant involvement of the apex as the primary focus of infection in human tuberculosis, Grober's claim that the mode of infection was commonly through the tonsil, and thence to the parietal pleura opposite the dome of the apex, misled pathologists for a time, until attention was called to the fact that the lymphatics of the tonsil empty into the deep cervical chain, and they in turn, together with the chain from the parietal pleura opposite the apex, empty into the great veins, in the angle of the neck, making it highly improbable that such a backward infection is possible. Latham's assertion that there may be, and probably is, a backward invasion of the lymphatics by the tubercle bacillus, also has never been confirmed by necropsy studies, and lacks the pathologic analogy in syphilis or anthracosis, both of which progress in the course of the lymph stream.

THE POSSIBILITY OF FOREIGN MATTER REACHING THE LUNGS THROUGH THE INTESTINAL TRACT

Several reliable investigators have demonstrated by animal experimentation that the continuous introduction of lampblack into the intestinal tract, over a long period of time, will produce well marked anthracosis. Weigert had demonstrated previously that the younger the animal the more readily did foreign matter pass the barriers of the lymph nodes. In old cows, pigmentation of the lungs, and bronchial and mediastinal glands, exactly corresponds to the anatomic fields invaded by the tubercle bacillus. Guerin and Grysez, working with Calmette, failed in numerous experiments to produce anthracosis in animals exposed to a constantly saturated atmosphere of lampblack if the esophagus was closed; but anthracosis invariably followed if the lampblack was introduced into the stomach by means of a tube, or if mixed with the food.

The same investigators proved by repeated animal experimentation that tubercle bacilli, introduced into the stomach by means of the esophageal tube, penetrated the intestinal mucosa without demonstrable lesions, the organisms being recovered at varying periods in the lungs and mediastinal glands. Nicolas and Descas fed tubercle bacilli to fasting dogs, and recovered the organisms in the chyle duct as early as three hours after ingestion. Ravenel and Klebs immediately paralleled this experiment by introducing into the stomach of dogs, by means of the esophageal tube, tubercle bacilli suspended in a mixture of melted butter and warm water, the organisms being recovered from the chyle ducts and mesenteric glands in less than three hours in some of the experiments.

Behring has shown that even the anthrax bacillus will penetrate the intestinal mucosa in a few hours.

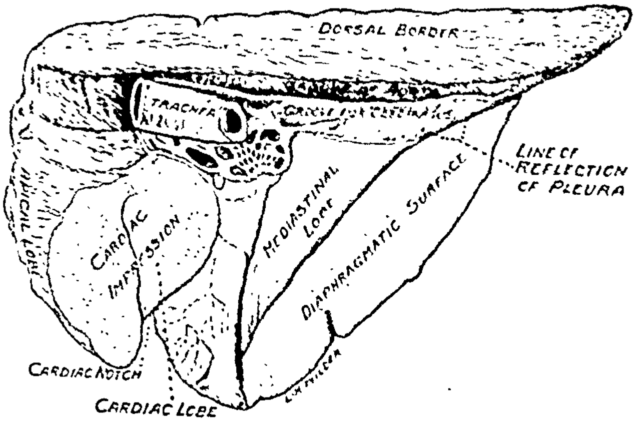

Fig. 2.—Lateral view of the bovine lung, the shaded portion of the tip showing the point of election. The bovine apical lobe also is frequently involved, but infection of the cardiac lobe, the most dependent portion of the bovine lung, rarely occurs, even in the last stages of the disease. From Sissons.

Schlossmann and Engel injected tubercle bacilli, suspended in cream, into the stomachs of guinea-pigs, and after six hours the animals were killed, and portions of lung tissue inoculated into other guinea-pigs, with positive results.

This experiment was also repeated by Ravenel, in a most careful manner, with positive findings. He opened the abdomens of guinea-pigs, and with a very thorough technic, introduced bacilli into the stomachs of the pigs by means of sterile needles, which were coated with paraffin, the intention being to avoid planting bacilli in the stomach wall while introducing the needle. The animals were killed at intervals of four and six hours, and portions of lung tissue injected into control guinea-pigs, with positive results. In another series, the animals were killed and examined at the end of six weeks. Nine out of ten had tuberculous foci in the lungs, besides more or less involvement of the thoracic and mesenteric glands.

Oberworth and Rabinowitch went a step farther in avoiding possible error in a similar series of experiments and succeeded in producing positive primary lung involvement, by feeding tubercle bacilli to young guinea-pigs through established gastric fistulas.

THE MODE OF INVASION IN HUMAN AND BOVINE TUBERCULOSIS

In analyzing the possible methods of infection of man with the tubercle bacillus, one is justified in basing fairly definite conclusions on experimental data that have been subjected to comparative pathologic analogies. Therefore, it is reasonable to assume that in whatever way the cow is infected it will be found that anatomically, the manner is not dissimilar in man; but at the very outset believers in the ingestion method, especially those who are wedded to the theory that milk is the prime factor in the spread of tuberculosis, are confronted with the confusing fact that the cow herself is not a milk feeder, notwithstanding her marked susceptibility to tuberculosis.

If one stops short here, and throws out of consideration the ingestion method of infection in bovines, then likewise one should exclude this method in the study of human tuberculosis; but the experimental data quoted above do not justify any such action.

As early as 1868, Chauveau produced pulmonary and general tuberculosis in young calves by feeding them ground material of diseased organs of tuberculous cows. Swine tuberculosis is undoubtedly by ingestion — nearly always by tuberculous milk. Experimentally, calves have been infected in this manner when the surroundings were otherwise controlled to prevent the possibility of contracting the disease by inhalation. Avian tuberculosis is by ingestion, without question.

The cow's infection is also by ingestion, notwithstanding the fact that she is not a milk feeder. A study of the habits of this animal is convincing that an infected cow spreads the contagion by explosive coughing, thus sending droplets of sputum in all directions, on her own food and on the food of her adjoining neighbors. Ravenel has proved that the cow does cough, and that she does throw off sputum in this manner.

Friedberger and Fröhner, long ago, called attention to the fact that when a tuberculous cow is placed in a stable, the disease progresses along a row, passing from one to another in regular order. Adams and Jobson made the interesting observation, on two different herds in which the cows were stalled in pairs, solid partitions as high as the animals' backs separating each pair from other pairs, that the tuberculous cow of the pair invariably infected her mate, but the cows in the adjoining stalls, if healthy, remained so.

Of course, this evidence in and of itself alone does not rule out the possibility of infection by inhalation; and yet, if viewed in the light of the methods by which swine and fowls contract the disease, it certainly deserves careful consideration.

There seems to be good ground for the stand taken by Aufrecht that tubercle bacilli gain the circulation, however introduced, and then traverse the blood vessels as foreign bodies until arrested, or until screened out in some organ, most commonly in the pulmonary terminal arteries. Here the bacillus passes the thin vessel wall barrier, to be picked up by lymphocytes, probably, and promptly carried to the nearest lymph node. That is the histologic picture of invasion in man and in animals. The pathologic picture does not come into view until a bacillus is arrested.

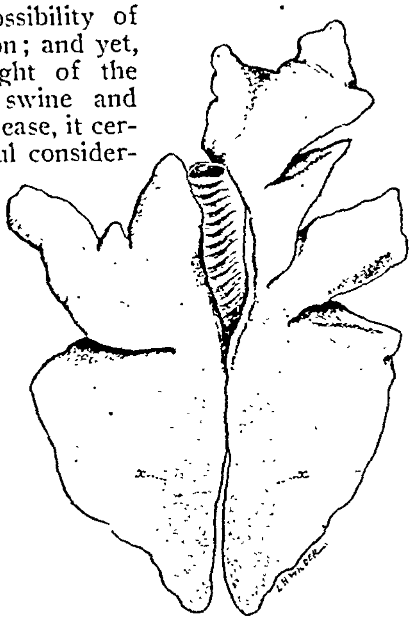

Fig. 3.—Superior surface of bovine lung, shaded portions marked x showing point of election. From Theobald Smith.

THE POINT OF ELECTION

Pathologists are now convinced that the tubercle bacillus, however introduced into the body, gains entrance to the circulation in man and in animals without demonstrable lesion. The final point of lodgment of the organism affords a wide field for theorizing, much of the vast literature on the subject of the initial site of pulmonary tuberculosis in man being wholly speculative, and often illogical, especially when subjected to the analogies of comparative pathology. It seems only fair to assume that whatever biologic or anatomic factor is advanced as the reason for primary involvement of the apexes in man, the same causes must apply in like manner to the initial site in the bovine.

The hypotheses that the two different bronchial angles subject one apex to greater exposure to infection on a particular side; the recent resurrection of Freund's theory to damage done to the apex by shortening of the first costal cartilage, followed by shortening of the first rib by ossification; the supposed unstableness of the apexes in mammalian life; vocational postural effects on the upper lobe; reversal of the respiratory rhythm; atelectatic zones, and many other similar assertions, fall to the ground in attempting to account for the point of election in bovine tuberculosis. If any of these fanciful theories appeal to the imagination, then it seems fair to insist that whatever causative factor is used to explain apical involvement in man, the same logic, under like conditions, should be applied to elucidate the point of election in the lungs of cattle.

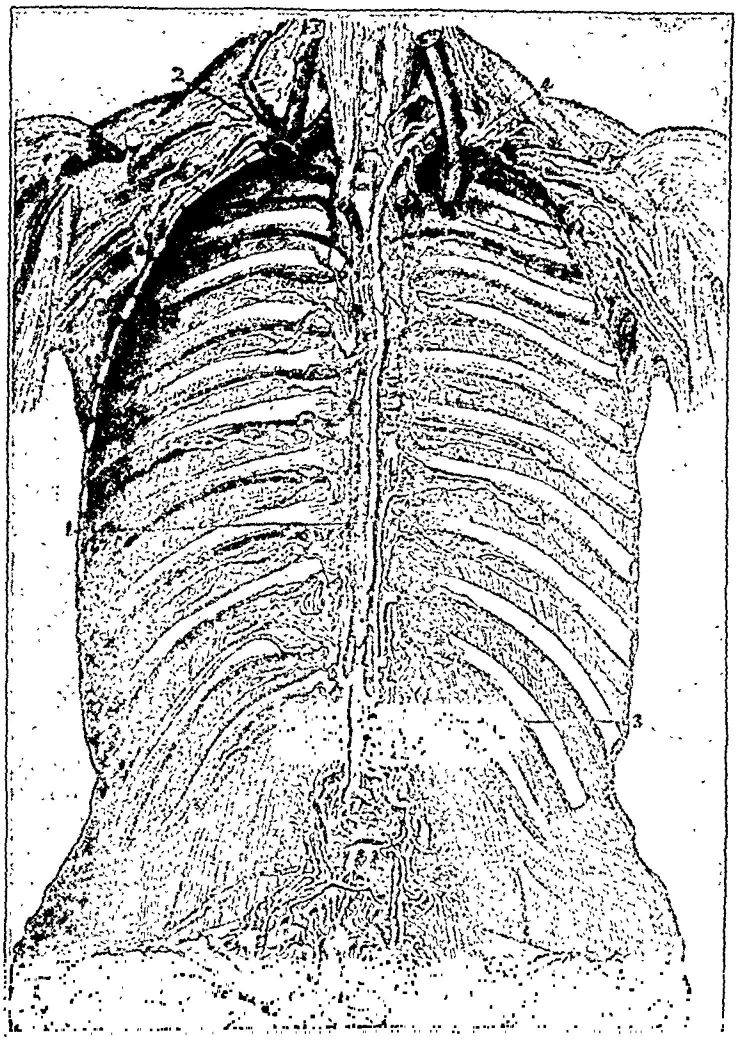

Fig. 4.—Thoracic duct, and the deep cervical lymphatics that anastomose with the parietal pleura opposite the apexes of the human lungs. By Mascagni. From Cuneo.

Pigmentation of the lungs in man, and in cattle, corresponds precisely to the fields of invasion of the tubercle bacillus. In man the apexes are the initial sites of demonstrable tuberculous foci. This is also true in anthracosis. In the cow, however, the initial lesion is at the very tip of the caudal lobe, the most superior portion of the bovine lung, anatomically corresponding to the most dependent portion of the human lung (Figs. 1, 2 and 3). This portion of the cow's lung is the most expansible, and has the best lymphatic drainage. None of the quoted hypotheses offers a reasonable explanation why this portion of the cow's lung is the point of election. The reason must be purely anatomic, for if bacilli first gain the blood stream through the lymph channels, then the pulmonary circulation must of necessity distribute them uniformly to all portions of the lungs, in cattle, as well as in man.

To emphasize a point, it is restated that in cattle, as well as in man, the deposits of foreign matter are anatomically the same as for tubercle bacilli. The lungs of old cows show the greatest pigmentation in the superior portion of the tip of the caudal lobes, which is shown in Figure 3. The shaded portions in the caudal lobes, maked *x*, are the points of election in bovine tuberculosis.

It has been repeatedly demonstrated that the very tip of the caudal lobe of the cow's lung is more generously supplied with lymphatics than any other portion of the lung. These vessels converge at the root of the lungs and empty into the peribronchial glands. Lying contiguous to, and just above the tip of the caudal lobe, is the large posterior mediastinal gland, which picks up the lymphatic plexus on the thoracic surface of the diaphragm, and those from the pericardium and lower portion of the esophagus. The esophagus, thoracic aorta, inferior vena cava and thoracic duct lie immediately above this gland. Exactly beneath the gland, as shown in Figure 2, and separating it from the lung tissue, are the parietal and visceral layers of the pleura, which enclose the pleural lake.

How this gland is infected, and why it shows such constant pigmentation, is the first and foremost problem to solve. In one series of fifty-three careful necropsies of tuberculous cows, Theobald Smith demonstrated that this gland was always involved when there was a focus in the caudal lobe, and in several instances the gland showed old, calcareous lesions, while the tip of the nearby caudal lobe, lying across the pleural lake, was probably invaded at a more recent date. Out of a series of over 40,000 necropsy studies of bovine tuberculosis in the Budapest abattoir, it was demonstrated that the infection in over one third of the cases was confined to the peribronchial and posterior mediastinal glands, a large percentage—figures not stated—of this number showing that the posterior mediastinal gland alone was involved. In one particularly interesting case, Mohler, of the United States Bureau of Animal Industry, demonstrated tuberculous foci in this gland in a five months' bovine fetus, with no other lesions in the carcass. In pseudotuberculosis, or caseous lymphadenitis of sheep, which certainly is not an inhalation disease, the same topographic involvement of the sheep's lung and posterior mediastinal glands takes place, just as with foreign matter and tubercle bacilli.

If one keeps the anatomy of this region of the thorax clearly in mind, especially the relations of the two pleural surfaces, it seems a reasonable belief that bacilli and pigmented foreign matter must cross the pleural lake, either from the lung side, upward to the gland, or from the gland, downward to the lung. The problem is confusing from either view, especially if the attempt is made to prove that the gland is first invaded, and the lung secondarily infected.

The reasonable conclusion is that bacilli and foreign matter are arrested in that portion of the lung shown in the shaded portion in Figure 3. At that point of the lung there must be an area of lymph stasis induced by the suction of the large posterior mediastinal gland, which, by means of a network of lymph vessels, drains that portion of the parietal pleura lying exactly opposite.

It seems fair to presume that the gland either receives its infection from the immediate underlying lung tissue, or that this portion of lung tissue receives its infection from the posterior mediastinal gland lying just above. In either event the pathologist is confronted with the fact that if bacilli are first screened out of the circulation at this point, or first penetrate the air vesicles, bacilli, and foreign matter as well, must pass through two layers of pleura to reach the gland; or if they are first screened out in the gland they must pass to the underlying lung tissue by the same route.

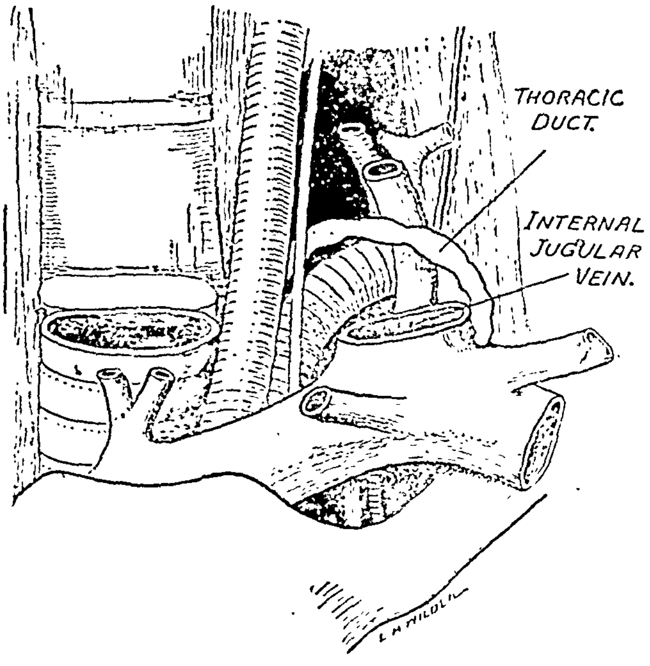

Fig. 5.—Terminal bend of the thoracic duct. From Cuneo.

That there are counter currents in the two pleural layers at this portion of the cow's lung is undeniable, and these counter currents, if they possessed any appreciable force, would most assuredly create a lymph stasis at a delimiting area somewhere between the points of suction. The mechanics of this assumed lymph stasis is not hard to understand if the anatomy of the great thoracic duct is held clearly in view (Fig. 4). This duct, as large as a good sized vein, is generously supplied with check valves throughout its course, to prevent a backward flow of chyle and lymph. Opposite the fifth dorsal vertebra, in the bovine, it receives a large lymphatic vessel from the enormous posterior mediastinal gland. The circulation in the thoracic duct is maintained almost wholly by means of the suction caused by the venous flow past the orifice of the duct at its opening into the subclavian vein (Fig. 5). The pull in the trunk of the duct would certainly influence the flow of lymph from the posterior mediastinal gland, and this in turn would drain the pleural lake in that area, and the visceral layer of the pleura, beyond. Then if the peribronchial glands have been previously damaged by invading organisms or by deposits of coal dust, accidental microscopic foreign matter falling within this exact zone of lymph stasis would most likely be temporarily arrested, with the subsequent formation of a focus of infection in the case of the tubercle bacillus.

If bacilli first reach the circulation, as most pathologists now believe, then there is no good reason to doubt that all portions of the human and bovine lung are exposed to an equal degree of infection or dosage, whether they enter the circulation by way of the alimentary tract, or are inhaled directly to the air sacs and then penetrate to the underlying interalveolar tissue. Tubercle bacilli have no selective power for any particular portion of lung tissue. Once they are arrested and gain a foothold, they will grow as rapidly in one portion of the lung as in another.

The lodgment, then, of bacilli and foreign matter by apparent selection in a special organ, and in the superior part of this organ, as is the case in both the cow and man, contrary to the clinical observation that pneumonia always attacks the lower lobe, and contrary to the laws governing ponderable matter, must be due to mechanical causes influencing them along unusual lines. In man, that portion of the parietal pleura lying contiguous to the apex of the lung is drained by a vast network of lymph vessels that empty into the deep cervical chain (Fig. 4). Nowhere else in the human thorax is there a decided counter lymph current; and granting that there is this counter current, it could account for an area of lymph stasis in the apex of the lung.

Study of the pulmonary lymphatic distribution in man shows that the apex, apparently, is not well protected by its separate set of small peribronchial glands. Reasoning from this fact alone, one is liable to jump to the conclusion that this seeming lack of glandular defense might account for the greater frequency of apical infection. Comparative pathology saves one from this error, however, as the point of election in the cow's lung has the greatest defensive lymphatic barrier. Carrying the analogy still further, it is the most plentifully supplied with lymphatics, and if posture has any bearing on the question, the caudal lobe, by its superior position in the thorax, has the best bronchial drainage. In fact, in taking any view of the method, or methods of infection in man, every anatomic or biologic argument that has been cited must apply with equal force in explaining the method of bovine infection.

CONCLUSIONS

Pulmonary tuberculosis, in man as well as in animals, is primarily an infection of the lymphatic vessels and lymph glands in the lungs.

Cough and expectoration are late manifestations of the disease.

With the experimental evidence at hand, it is a fair assumption that, commonly, infection in man and animals is by the ingestion method.

Even where the bacillus is planted on the respiratory mucous membranes by means of dried sputum, or by dried feces, as is often the case with cattle, the anatomic method is still by the intestinal tract, for the reason that the number of bacilli that would be swallowed under such conditions is out of all proportion to the very doubtful number that might possibly reach the air vesicles by inhalation.

The granting that infections are commonly by the intestinal tract does not lessen at all the potential danger of infected dust, as much of this dust would be swallowed, even though planted on respiratory mucous membranes by inhalation.

All portions of the lungs, in man and in animals, are invaded with dust and tubercle bacilli in equal measure, whether the route be through the trachea or through the intestinal tract.

The lower, as well as the upper, peribronchial glands are equally pigmented in anthracosis, and roentgenograms show the same involvement in early tuberculosis. Pigmentation and infection of the lower lobes in man do not appear until the defenses of the peribronchial glands are permanently damaged.

No portion of the lung possesses a specific biochemical constituent that would sensitize it to the tubercle bacillus, nor does the bacillus possess selective properties for any special portion of the lung.

Whatever exact reason exists for the constant invasion of a specific area in the lungs of man and cattle, the causes for this point of election must be wholly physio-anatomic.

SODIUM AND POTASSIUM IODIDS IN ROENTGENOGRAPHY

DONALD F. CAMERON, A.M., M.D.
Fellow in Surgery, University of Minnesota; Passed Assistant Surgeon, U. S. Naval Reserve Force
ST. LOUIS
AND
CHARLES C. GRANDY, A.M., M.D.
Pathologist and Roentgenologist, Lutheran Hospital
FORT WAYNE, IND.

A few weeks ago, in a preliminary report,[1] attention was called to some experimental results in the use of potassium and sodium iodids as opaque mediums in roentgenography. Since this report was made, these solutions have been put to practical use in a sufficient number of cases to warrant a report of their clinical application.

PREPARATION OF SOLUTIONS

For pyelography, a 25 per cent. aqueous solution of sodium or potassium iodid is used. Thus, 100 gm. of solution is made by dissolving 25 gm. of the salt in 75 c.c. of water. For cystograms, a 15 per cent. solution gives sufficient density. As was noted in the previous article, these solutions are stable, neutral in reaction, and cause no precipitation in urine or bloody urine. On standing, they become slightly yellow, but this causes no trouble. There are no special precautions to be observed in preparing the solutions, and they are easily sterilized by boiling.

CLINICAL RESULTS

These solutions have been used by us or in our presence in eight human cases, which have included the examination of two bladders, three kidneys and three chronic sinuses. In all cases the roentgenograms have been entirely satisfactory. The pyelograms were made with solutions varying from 25 to 33 per cent. in strength, the potassium and sodium salts being used interchangeably. A 25 per cent. solution of the sodium salt casts a shadow sufficiently dense for all purposes, though a denser solution may be safely used if greater contrast is desired. For cystograms, a 15 to 20 per cent. solution of either salt is used.

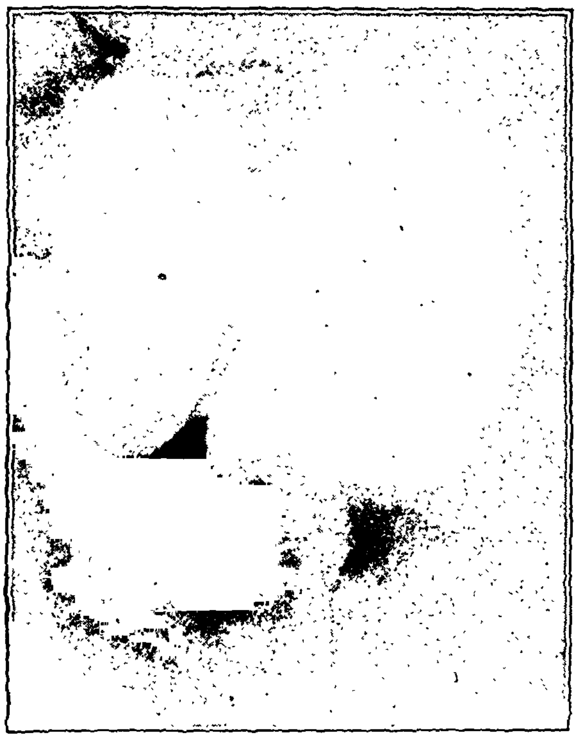

Fig. 1.—Cystogram of bladder filled with 15 per cent. solution of sodium iodid; patient of Dr. Bransford Lewis. In addition to the large diverticulum, the prostatic cavity is shown. The prostate gland had been removed elsewhere some time before. (Courtesy of Drs. Bransford Lewis and Neil S. Moore.)

As regards pain or discomfort to the patients, in making the two cystograms, there was no complaint of any kind in either case. In making the pyelograms, there was complaint of some pain over the bladder and along the course of the ureters, but no more than is often seen following ureteral catheterization alone. Since the solutions when introduced into the bladder caused no unusual sensation of any nature, it is probable that the discomfort in filling the kidney pelvis was due to mechanical causes and not to the character of the solutions. The patients walked to their homes after the pyelograms were made, and complained of no further trouble. One voided a small quantity of blood-tinged urine after the ureteral catheters were withdrawn; after this, and in the other cases, the urine voided was unchanged in character. The large bladder diverticulum, shown in Figure 1, was removed by Dr. Lewis four days after the cystogram was made. At operation the bladder showed no sign of any irritation due to the solution used.

In view of this experience, though rather limited in quantity, we feel reasonably safe in recommending these solutions for this kind of work.

After one of us had been ordered to duty in St. Louis, we were fortunate in having Drs. Bransford Lewis, J. R. Caulk and H. G. Greditzer volunteer to use the solution. We acknowledge their kindness in allowing us to use the accompanying illustrations.

CHOICE OF SOLUTIONS FOR PYELOGRAPHY

Colloidal silver solutions are quite satisfactory for this work. These solutions, however, are relatively expensive, and in addition possess undesirable physical properties. In the past three years the thorium solution introduced by Burns[2] has become very popular. Its cost is much less than that of colloidal silver of equal density, it is a clear solution, it does not stain, and it has a relatively low viscosity. A little more than ordinary care is necessary to prepare the solution, it being necessary to neutralize the aqueous solution of thorium nitrate, which is acid in reaction, and to add sufficient amount of sodium citrate to keep the thorium from precipitating. Though this is not at all a difficult procedure, most users have preferred to buy the prepared solution which, as sold at present, affords the makers a considerable profit. At present thorium salts are rather difficult to obtain and are not listed by several large wholesale chemical firms which formerly kept them. At the present retail price of sodium and potassium iodids, a 25 per cent. solution of these salts is about half as expensive as the prepared 15 per cent. thorium solution. The sodium salt is a little more expensive than the potassium, and in the same concentration gives a slightly denser shadow for the reason that its relative iodin content is higher. These iodid solutions have all the desirable features of the thorium preparation, and in addition are made with much less trouble, are less expensive, and the ingredients are obtainable at any drug store. In the event of absorption in ordinary amounts, these salts are known to be nontoxic.

---

[1] Cameron, D. F.: Aqueous Solutions of Potassium and Sodium Iodids as Opaque Mediums in Roentgenography: Preliminary Report, The Journal A. M. A., March 16, 1918, p. 754.

The prevailing retail price of a pint of the silver, thorium and iodid solutions of the same density is about $10, $5 and $2.50, respectively. The wholesale price is approximately 25 per cent. less.

THEORETICAL CONSIDERATIONS

It is obvious that a sufficiently concentrated solution of any iodid or element of high atomic weight will be opaque to the roentgen ray. For use in pyelography, however, these solutions must be nonirritating and nontoxic, and must not form precipitates with urine or bloody urine. These restrictions limit the field considerably. From a more or less systematic survey of the common chemical substances that might be used, the iodid solutions recommended seem to be most suitable. On general principles it would seem better to have solutions of lower osmotic pressure. Aside from using colloidal solutions, this result could be obtained by using salts whose molecules in solution contain several atoms of high atomic weight which are not ionized to a high degree. Thorium iodid came to mind as a possibility. This could not be obtained on the market, and in any event its scarcity and expense would rule it out. Strontium iodid has several properties to recommend it. It is easily obtained, is nontoxic, and is not very expensive. It forms a neutral solution in water, and a 20 per cent. solution casts a good shadow under the roentgen ray. The one objection to its use is that when mixed with urine a very light, flocculent but appreciable precipitate occurs, requiring some time, however, to form and settle. Though this is not so serious, it should be a bar to its use in cavities which cannot be well irrigated. Other iodid and heavy metal solutions were tried, but none were found which are so free from objections as the two recommended.

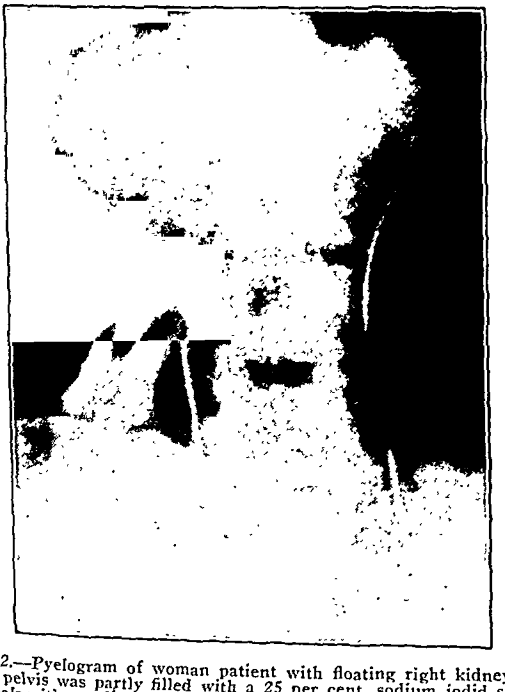

Fig. 2.—Pyelogram of woman patient with floating right kidney. The kidney pelvis was partly filled with a 25 per cent. sodium iodid solution. The malposition of the kidney prevented a better technical result. (Courtesy of Dr. H. G. Greditzer.)

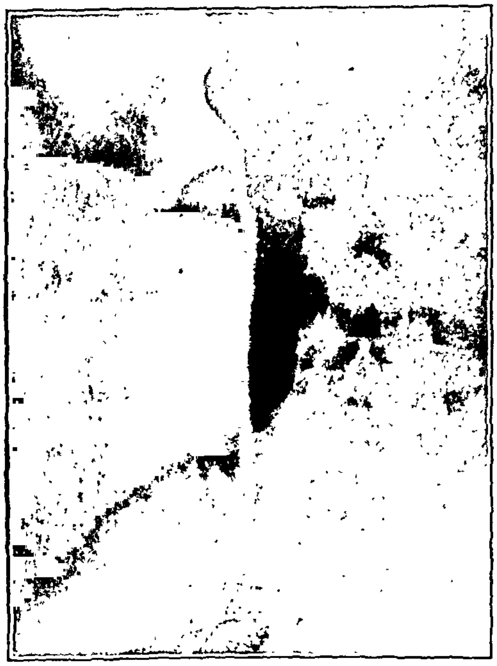

Fig. 3.—Pyelogram of right kidney of a man. A 33 per cent. potassium iodid solution was used. (Courtesy of Dr. H. G. Greditzer.)

SUMMARY

1. Excellent pyelograms have been obtained through the use of from 25 to 33 per cent. aqueous solutions of sodium or potassium iodids as opaque mediums. A 25 per cent. solution of the sodium salt is recommended for this work, though if greater contrast is desired, a stronger solution may be used. A 15 to 20 per cent. solution is sufficient for good cystograms.

2. These solutions have been used, either by us or in our presence, on eight patients. No undesirable effects of any nature have been noted.

3. The solutions are made by dissolving the proper amount of the salt in water. The solution thus formed is neutral in reaction, quite saline in taste, but nontoxic and nonirritating to the bladder or kidney pelvis, and causes no precipitation when mixed with urine or blood-tinged urine. Of all solutions used in pyelography, we are familiar with none so easily made and so inexpensive.

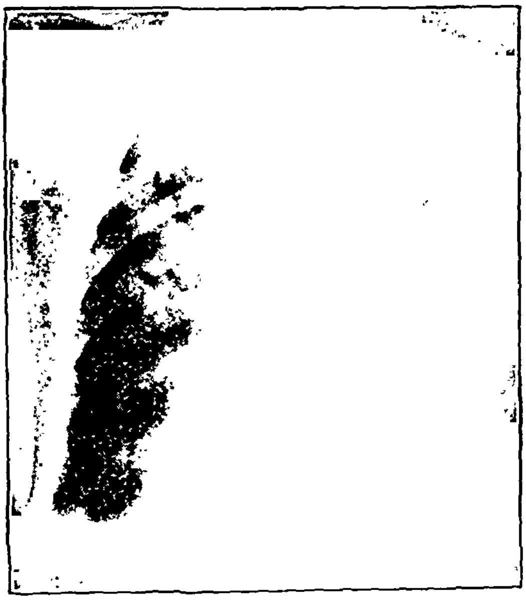
A CASE OF DOUBLE SPONTANEOUS PNEUMOTHORAX *

M. I. MARSHANK, M.D.
EDGEWATER, COLO.

Spontaneous or natural pneumothorax is not an infrequent complication in pulmonary tuberculosis. Double spontaneous pneumothorax, however, is exceedingly rare. In a review of the indexed literature I was unable to find a single case report on record.

REPORT OF CASE

I. S., a man, aged 50 (Case 2714), a merchant, admitted, Jan. 2, 1917, presented a negative family history, aside from the fact that the father died of probable pulmonary tuberculosis. The patient had measles during childhood, but had made a good recovery with no complications. No other illness was noted until the onset of pulmonary tuberculosis about 1905. The type of onset was insidious, with anorexia, loss of weight, cough, expectoration, and night sweats. The patient later developed pain in the right axilla, and occasional streaked sputum. The sputum was found positive at that time. Since the onset in 1905, the patient had been subject to frequent colds and to attacks of sore throat. He wandered over a considerable portion of the United States in search of health, and eventually came to Denver, Jan. 2, 1917, to be admitted to the Sanatorium of the Jewish Consumptives' Relief Society.



Right side: Complete collapse with fluid to fourth rib. Pneumothorax of longer standing. Left side: Acute type of pneumothorax, partial in extent.

On admission the symptoms were severe cough (worse at night and on lying down), expectoration, occasional chills, temperature rising to 100 F. in the afternoon, with a pulse range of from 80 to 104. There were no night sweats, weakness was marked, and there were occasional blood streaks in the sputum, which was positive for tubercle bacilli. Dyspnea was marked on the least exertion. There was rather severe pain over the right side, which had been present, off and on, during the past twelve years. The appetite was good and the bowels were regular.

The patient was markedly emaciated, and looked more than 60 years of age. He was somewhat cyanotic, with marked depressions above and below the clavicle, in both suprascapular and infrascapular spaces, and in the intercostal spaces. The secondary muscles of respiration were markedly developed, the costal angle was acute, the glands were not palpable, the skin was dry and somewhat scaly, the hair was sparse and dry, the eyes, nose, throat and ears were normal, there were no pulsations in the neck, and the thyroid gland was not enlarged.

The heart was to the right, the right border being at the right nipple line. The left border was under the sternum. The sounds were normal, the radial arteries were palpable, the superficial veins on the extremities were dilated, and the venous flow was sluggish. The systolic blood pressure was 94, and the diastolic, 64. The abdomen was negative. The liver, spleen and kidneys were not palpable. The urine was normal. There was a marked tenderness over both posttibials, the reflexes and the bones and joints were normal, and the muscles were atrophied throughout. The chest examination revealed infiltration to cavity formation throughout both lungs. There was a tendency to hyperresonance over both lungs which we thought was due to associated emphysema. No signs of fluid and no splash were present.

The patient left the institution, Feb. 12, 1917, after a disagreement with a fellow patient, and went to live at a farmhouse a few blocks distant from the sanatorium. A few days later we heard that he was very ill and had a great deal of pain on the right side. He was up and about in a few days. March 4, Dr. Joseph W. Craighead saw him and, although the patient was so sick and in such severe pain that an examination could not be properly made, he made a diagnosis of spontaneous pneumothorax, from the symptoms observed. A few hours later when admitted to the sanatorium the patient was moribund, and twenty minutes later he died.

To verify our diagnosis, a necropsy being unobtainable, we examined the body by fluoroscopy and discovered a right-sided pneumothorax with fluid. This being of sufficient interest, we made a roentgenogram of it. On developing the plate we were much surprised to find what looked like an acute pneumothorax on the left side.

We concluded that the patient developed the pneumothorax on the right side soon after leaving the sanatorium, and that the pneumothorax on the left side developed, March 4, and diminished his breathing space sufficiently to produce death.

ARTIFICIAL PNEUMOTHORAX IN THE TREATMENT OF PULMONARY TUBERCULOSIS

RESULTS IN PRIVATE AND DISPENSARY PRACTICE

ALVIS E. GREER, M.D.
HOUSTON, TEXAS

The basis of this report is a record of thirty-two cases of pulmonary tuberculosis treated by an artificial pneumothorax of nitrogen gas during a period of three and one-half years. It has been claimed that a sanatorium regimen is an essential element in the management of patients treated by pulmonary compression. Our results in this series will, I hope, disprove the necessity, although I fully admit the advantages of sanatorium treatment, and cause us to realize that a great deal can be done for the many patients at home, unable or unwilling to seek the western sanatoriums for relief.

These cases were taken chiefly from the material afforded by the Houston Anti-Tuberculosis League Clinic, and the patients were in many instances unable to procure the rest and nourishment prescribed for them. Nineteen men and thirteen women were treated for an average period of six months each; three patients were treated for eighteen months each; four for one month each, and the other patients for varying periods between. The patients were classified as seven, or 22 per cent., in the first stage; fourteen, or

44 per cent., in the second stage, and eleven, or 34 per cent., in the third stage. Their ages varied from 15 to 60 years. Our first seven cases were selected chiefly because they were seemingly hopeless. But later we began to discriminate more closely as we came to realize that in this procedure we had an exceedingly effective measure for assisting these unfortunates in arresting their disease.

A Floyd-Robinson apparatus was used, and the operation was performed under procain (novocain) and epinephrin anesthesia. The physical examination was, in most cases, supplemented by a careful roentgen-ray examination. An effort was made to secure unilaterally involved cases, or patients with slight involvement of the untreated lung. The degree of activity of the untreated lung is of more consequence than the amount of lung tissue involved per se. This is because a relatively larger area of nearly quiescent tuberculous lung tissue will bear the strain of having to act vicariously for the collapsed lung better than a smaller area of actively diseased tissue. As will be seen in the case reports, this ideal was not possible because we had to accept the material available for treatment. Twelve of the patients had involvement of the untreated lung, which was of a more or less inactive type. An area without cavities and râles in the untreated side, even involving the greater portion of a lobe, will offer a better prognosis than a small, active focus in that lobe. It is unwise to treat any case, except palliatively, which presents a tuberculous focus in the untreated basal lobe. The opposite lung, acting vicariously for its compressed mate, and therefore subjected to greater expansible effort, will more readily activate a focus in the base where the expansile mobility is greatest. All the eleven rather extensively involved bilateral cases presented signs of cavity in the treated lung; while in the opposite, that is, the better lung, none of the cases had any sign of cavation.

SUMMARY OF THIRTY-TWO CASES

* In this column, ♂ denotes male, and ♀ female.
† In this column, H. S. means American nativity.

The technic is comparatively simple, and the operation safe, if the indications are rigidly followed. It is self evident that, for the successful performance of the operation, pleural adhesions should be at least limited in extent, and preferably nonexistent. In 15⅔ per cent. of our cases, we encountered troublesome adhesions which prevented us from carrying out the treatment. The use of the fluoroscope is of the greatest value in this particular, although it is possible in a majority of the cases to determine the presence of adhesions by the usual methods of physical examination. With a well marked Litten's sign and fair basal excursion, and the absence of marked chest retraction, it is reasonable to assume that troublesome adhesions are absent. The choice of the site of puncture is usually at the fourth or fifth interspace in the anterior axillary line, or at the angle of the scapula. It is well to percuss lightly the area to be elected, and unless a fair quality of resonance is present, adhesions are liable to lie beneath, and another site should be chosen.

I shall not attempt to describe every case in detail, but shall give a summary of the histories of six cases, classifying them as follows:

1. Hopeless, bilaterally involved, advanced tuberculosis (Case 1).
2. Chronic, bilaterally involved, fibroid tuberculosis (Case 2).
3. Acute pneumonic tuberculosis (Case 3).
4. Pulmonary hemorrhage (Case 4).
5. First-stage tuberculosis (Case 5).
6. Chronic tuberculosis, with a large cavity in the compressed lung, and moderate involvement in the better lung (Case 6).

REPORT OF CASES

Case 1.—W. E. N., aged 47, an American carpenter, married, had suffered from the disease one year before the first examination. The disease was extensively bilateral, most marked in the right lung with signs of cavity in the right upper lobe. As a third-stage case, it was hopeless. The patient was bedridden, expectoration was profuse, and there were night sweats, dyspnea and high temperature. Artificial pneumothorax on the right side was begun, June 3, 1914. The temperature dropped to 99 F. in the afternoon, and for four months was never above 99.2. The patient improved wonderfully. The sputum decreased, the night sweats stopped, the appetite improved, and the patient gained in weight and strength until he could get out of bed at will. In November, a right-sided pleural effusion appeared which partially compressed the lung until the patient's death in March, 1915.

Case 2.—F. S., a widow, aged 48, an American, referred by Dr. C. C. Green, gave a history of loss of weight, slight expectoration, night sweats, and afternoon fever—symptoms that had been present for the previous three years. The woman was frail, with extensive involvement of the right upper lobe, and of the right middle lobe to a lesser degree. The lower lobe was slightly involved, with considerable fibrosis throughout the right lung. The apex of the left lung was also slightly involved; the lower lobe was practically normal. Artificial pneumothorax was begun, Feb. 6, 1915, in the right pleural cavity. Some difficulty was experienced because of pleural adhesions, and only a partial collapse was secured. Injections were continued at intervals until July. Meanwhile, between that time and the previous date of April 25, she had been absolutely free of fever. In July the injections were discontinued, and for a number of months the patient improved and continued to do well. Her surroundings were poor and she took practically no care of herself from that time on. May, 1917, she reported that she was not doing well at all and she looked very thin, coughed a great deal and expectorated considerably.

Case 3.—G. P., a schoolgirl, aged 15, American, had suffered from the disease for six months. She complained of high afternoon temperature ranging from 102 to 103 F., of drenching night sweats, of loss of weight, etc. The right upper lobe and the upper part of the right middle lobe were involved throughout. The right inferior lobe was practically normal. The left apex showed a slight involvement. The left lower lobe was normal. Artificial pneumothorax was induced in October, 1915, and within a few weeks' time after this procedure the patient showed great improvement. Injections were continued until the following July. By this time, she had gained 20 pounds and I decided it would be safe to stop the injections. In two months' time, however, she began to have some cough and slight afternoon rise of temperature. There were a few râles in the right upper lung. The right pleural cavity was again injected and the compression has been continued until the present date. She has been without fever and any symptoms of tuberculosis for months, and at the present time I consider her case arrested.

Case 4.—M. H., a man, aged 27, American, single, sailor, reported that this present trouble had begun about a month and a half before the first injection, with cough, night sweats, and loss of weight, appetite and strength. He had been expectorating a considerable amount of purulent sputum. Two days before he was seen, he had a pulmonary hemorrhage of rather large amount. This was followed in about twelve hours by a second hemorrhage of rather large amount. This was followed in about twelve hours by a third hemorrhage. Since that time he had been coughing up a considerable amount of black blood. Examination revealed dulness, and a great many bubbling râles in the left upper lobe. Nitrogen gas was injected at intervals of two days until the lung was collapsed. After this, there was no further hemorrhage, and ten days later the patient reported that he had greatly improved. The highest temperature after the injection was 99.4, and after that time it was normal. He had very little expectoration, the sweats stopped, the appetite improved and he gained a great deal in weight and strength. March 9, the patient had a hemorrhage of about 2 ounces of bright red blood. I injected 1,200 c.c. of nitrogen gas into the left pleural cavity. There was no further hemorrhage, and the improvement has continued until, at the present time, the disease is arrested.

Case 5.—L. A. H., a housewife, aged 28, American, was referred by Dr. Gavin Hamilton. The trouble began in January, 1916, with hemorrhage, after which she began to decline in weight. There was very little expectoration, with afternoon rise of temperature ranging from 99 to 100. Examination revealed a frail woman weighing 93 pounds with tuberculosis of the right upper lobe. The diagnosis was confirmed by the roentgen ray. February 22, artificial pneumothorax of the right pleural cavity was begun. The injections continued without incident until March 10, 1917. In June, 1917, she presented no signs of the disease, had no abnormal temperature, cough nor night sweats, and had gained 28 pounds in weight. The case was arrested.

Case 6.—R. H., a bricklayer, aged 30, American, single, referred by Dr. C. U. Patterson, had been ill with the present trouble since November, 1915. The patient complained of free and purulent expectoration, night sweats, considerable afternoon rise of temperature, and loss of 30 pounds. Examination revealed a man weighing 140 pounds with involvement of the upper and middle lobe and, to some extent, the lower lobe of the right lung. There was a cavity in the lower portion of the right upper lobe. The left upper lobe also was somewhat involved. Artificial pneumothorax of the right pleural cavity was begun, March 19, 1916. Further injections were without incident, and the injections were continued at intervals until April 6, 1917. For many months afterward, this patient had no abnormal temperature, and expectoration gradually ceased. In June, 1917, the patient was at work as a night detective, and he said he felt absolutely well. At that time his weight was 172 pounds, a gain of 32 pounds since the beginning of the treatment.

COMMENT

The decided improvement noted in Case 1 was more than we expected. The man's life was prolonged for months. During this period he was more comfortable than formerly. Patient 2, with fibroid chronic tuberculosis, was temporarily benefited, but the improvement was not permanent. In my opinion, such cases are not suitable for artificial pneumothorax, and should not be treated by this method unless large unilateral cavities with profuse expectoration are present. In our cases of acute pneumonic tuberculosis, the improvement was striking. The patients improved rapidly, showing a cessation of night sweats, a marked lessening of the cough, a stopping of the expectoration, a rapid declination of temperature, and a steady gain in weight and well-being. In five cases, pulmonary hemorrhage was successfully combated, and in three of these the pulmonary process was subsequently arrested. We have departed from the beaten path in advocating artificial pneumothorax in unilaterally involved first-stage cases, as exemplified in Case 5. The result in this case was excellent, and the patient is now well. Case 6 demonstrates a type of pulmonary tuberculosis in which the patient may be greatly benefited by an artificial pneumothorax. As was noted in this case, the improvement was rapid in onset and lasting in duration.

A great deal has been written in regard to the question of technic. I have purposely omitted this feature of the work. I should like to suggest in passing, however, that it is better to inject small amounts of nitrogen gas, from 300 to 500 c.c., at short intervals, than to use larger amounts at longer periods. Several of my earlier patients have received temporary setbacks because I injudiciously used from 1,000 to 1,200 c.c. of gas at single injections. It has seemed to me that pleural effusions have more frequently followed in these cases. On several occasions, high fever with severe vomiting ensued, which, however, ceased in a few days.

No cases of pleural shock, pleural infection, gas embolism, harmful puncture of the lung, or cardiac dilation were encountered. If these dangers were so formidable, this circumstance seems the more striking, because our patients, in many instances, were injected without prolonged preliminary observation, and in every case at the patient's home or in the office. Subcutaneous emphysema was frequently encountered in the earlier cases. But it was never alarming, although in one case the gas infiltrated into the tissues of the neck. We believe that the earlier cases presented this feature because we injected a large amount of gas, and allowed the patients to get out of bed too soon. Excessive coughing will cause this complication, as was demonstrated in one case. The use of a sharp needle for the subsequent refilling injections will aid in obviating subcutaneous emphysema.

In 20 per cent. of the cases treated, pleural effusions occurred. No attempt was made to withdraw this fluid, as the amount was never large. The injections were continued as before, except that smaller amounts were given at longer intervals. We have begun to look on this complication as favorable, because every patient has been benefited when an effusion occurred.

Because of pleural adhesions it was impossible to perform the operation in five of the thirty-two cases. All these five patients are now dead. In three other cases the continuation of the treatment was refused, and only one of these is living. Of the eight untreated patients only one is alive, and he is in very poor condition. Twenty-three of the other twenty-four patients are living. The patient who died (Case 1) was a hopeless third-stage consumptive. As four, or 12.5 per cent., of the total number of cases, were unimproved by the treatment, it was discontinued. Nineteen, or 80 per cent., of the twenty-four patients treated were greatly improved. Of these, six, or 20.5 per cent., were classified as improving, and thirteen, or 54 per cent., as arrested. It is significant that 96 per cent. of the patients treated are living.

The improvement in the patients' clinical symptoms was in most cases very rapid. The fever ceased, or fell considerably, night sweating ceased, the sputum decreased, the appetite improved, and the patient gained rapidly both in strength and weight.

CONCLUSIONS

We feel that a procedure which will bring about an arrest in 44 per cent. of the cases, or 32, in which the method was tried, and 60 per cent. of the cases treated, has a well established place in our therapeutic armamentarium. First-stage cases unilaterally involved should be treated by an artificial pneumothorax, and I am of the opinion that the time is not far distant when it will be more generally done. In the future we should select our cases more carefully, and give the earlier first-stage cases the benefit to be derived from an artificial pneumothorax.

Clay Pipe as a Breast Pump.—According to *Le Nourrisson*, a woman seeking a position at Paris as a wetnurse kept her breasts in good condition by pressing the bowl of a clay pipe over her nipple, and sucking the milk herself through the pipe-stem. This autosuckling breast pump by means of a tobacco pipe was suggested by Mesnard in 1743 to spare fissured nipples.

THE MARGIN OF ERROR IN THE DIAGNOSIS OF NEUROSYPHILIS OF THE PARETIC TYPE

IRA A. DARLING, M.D.
WARREN, PA.

The study of our errors may injure our vanity, but if honestly made and executed, it proves a healthy "mental catharsis" and materially aids our general understanding. In 1910, Southard[1] reviewed forty-one cases of clinical neurosyphilis of the paretic type that had come to necropsy at the Danvers State Hospital, and found an error of 15 per cent. in those cases that the staff had unanimously considered to be general paralysis of the insane. At the same time, the necropsy reports in 186 cases in which this disease was not considered clinically were studied, and two of these were found, by the plasma cell criterion, to be general paralysis of the insane. The cases considered in Southard's paper were diagnosed before the general application of biologic tests, and it is my present purpose to determine whether this addition to our diagnostic technic has been beneficial, or whether it has made us careless in our clinical examination to such an extent as to vitiate its usefulness.

The accompanying table shows at a glance the important points found in a study of 168 patients admitted to the Warren State Hospital between January, 1913, and January, 1918, and examined at necropsy. For the sake of comparison, figures taken from Southard's paper are placed in an adjoining column.

CLINICAL DIAGNOSIS AND NECROPSY FINDINGS IN NEUROSYPHILIS OF THE PARETIC TYPE

	Darling	Southard
Number of cases studied	168	227
Number of cases unanimously diagnosed as neurosyphilis of the paretic type	45	41
Number of cases unanimously diagnosed as neurosyphilis of the paretic type and proved to be that disease at necropsy	45	35
Number of cases about which opinions were divided, with some favoring neurosyphilis of the paretic type	6	20
Number of cases about which opinions were divided, with some favoring neurosyphilis of the paretic type, and proved at necropsy to be that disease	0	8
Number of cases proved to be neurosyphilis of the paretic type at necropsy, but not diagnosed clinically	0	2

The pathologic diagnoses of these cases are based on records made by Dr. Paul G. Weston, to whom I am indebted for aid in their interpretation, and also for making additional microscopic examinations in all doubtful cases. A final diagnosis of neurosyphilis of the paretic type is here based on the presence of ependymitis, chronic lymphangitis, and varying degrees of pial edema in the gross specimen; with cortical gliosis, perivascular infiltration with plasma and round cells, endothelial proliferation, presence of stab cells and disarrangement of cortical architecture in the microscopic section.

From the table it is seen that all of the forty-five cases unanimously diagnosed as neurosyphilis of the paretic type were proved at necropsy to have been that disease. It is worthy of note that every one of these patients was found to have a positive Wassermann reaction[2] in the spinal fluid at some time, and that all of those admitted after July, 1914,[3] gave a paretic colloidal gold curve[4] when the spinal fluid Wassermann reaction was positive. In several of these cases there were argument and divergence of opinion relative to the possible presence of complicating factors, such as epilepsy, gross sclerotic lesions, and toxic conditions secondary to heart and kidney disease. In spite of this, a definite preference for paresis as the basic condition was expressed by every one present at the conference.

[2] Weston, P. G.: Jour. Med. Research, 1914, **30**, 377 (Wassermann technic used).

[3] Prior to 1914, the colloidal gold test was not a routine procedure.

[4] Weston, P. G.; Darling, I. A., and Newcomb, P. B.: Am. Jour. Insan., 1915, **71**, 774 (colloidal gold test used).

There were six other cases which some of the staff members believed to be paresis, but concerning which the opinions were not unanimous. When these patients were examined microscopically at necropsy, none of them showed evidences of cerebral syphilis. It is also interesting to observe that five of these six patients failed to give positive serologic signs of syphilis in either the blood or the spinal fluid, and that the sixth patient died before any specimens for laboratory tests could be obtained.

I believe that many errors are made by placing too much dependence on one laboratory examination of the blood and spinal fluid. Several workers have drawn attention to the fact that the blood of a syphilitic will frequently be found negative to the Wassermann reaction at one time and positive at another. The records of the Warren State Hospital show many instances of this and also numerous similar irregularities in the findings in the spinal fluid examinations. Because of this recognized liability to variation in serologic findings, all the physicians presenting cases before the hospital staff have been very careful to have several specimens of blood and spinal fluid examined in all questionable cases before asking the staff to aid in the final classification, and this has, without doubt, aided materially in making accurate diagnoses.

These findings confirm the opinion that I expressed[5] in 1915, namely, that with the aid of modern laboratory methods, probably 100 per cent. accuracy could be obtained. It does not necessarily follow that this high percentage could be maintained indefinitely; but the facts presented in this study prove that the error in diagnosing neurosyphilis of the paretic type can be made almost negligible if a careful clinical examination is combined with repeated serologic tests made by a competent laboratory worker.

---

School Lunches.—Along with other sociologic problems of increased importance during the war, the subject of school lunches for children in the large cities, particularly, has been the subject of augmented interest. The New York School Lunch Committee, maintained by the New York Association for Improving the Condition of the Poor, has published information concerning the work of the committee in New York, where lunches are provided in thirty-five of the 208 schools of the city. On account of the increased cost of everything, the price of the dishes of these lunches has had to be raised somewhat, and still the income has not equaled the expenditure for food and service, to say nothing of the cost of equipment. The income from lunches in thirty-four of the schools during the period from 1916 to 1917 was $38,369.81, while the operating costs, including capital expenditures, amounted to over $60,000, leaving a deficit of nearly $22,000. The need for this work has been demonstrated, and its good results have been apparent not only in the benefit derived by the children, but also in the example set for the parents at home, where diet conditions have been improved. The committee says that there is an almost universal belief among those who have seriously considered the problem that school lunch work is school work and should be taken over by the board of education. Heretofore, the funds have come from public-spirited citizens.

THE PRESENCE OF SPIROCHETES IN THE KIDNEY *

YUTAKA KON, M.D.

AND

TOMOMITSU WATABIKI, M.D.

TOKYO, JAPAN

In May, 1917, at Tokyo, Futaki demonstrated spirochetes in the urine and the renal casts of typhus-infected kidneys, and reported them as the specific causative agent of typhus fever. Two months later, Futaki's report was discussed by Miyashima, Kusama and Koga. Miyashima and Kusama had not been able to find any spirochetes in the kidneys or other organs of experimental typhus-infected animals (rabbits and guinea-pigs). Koga had found many spirochetes (the *Spirochaeta smegmatis?*) in the urine of patients suffering from different diseases and also in healthy persons, but he could not find any points in which morphologically the spirochetes differed from the spirochetes of Futaki. There was, however, a stronger pulse than in the presence of spirochetes in the kidneys. For control examination, we observed many kidneys, which were mostly affected

by acute and chronic nephritis, in which casts were present. These we stained by Levaditi's method. We found many silver-stained spirochete-like bodies in the casts of kidneys in different diseases. It may be said, therefore, that the question of the presence of spirochetes in the kidneys in various diseases other than typhus fever is such an interesting problem that more attention should be paid to it. We have examined many kidneys in both dead and living bodies harboring various diseases, and we here record the results of our observations.

We have examined fifty kidneys of dead bodies and twenty-six of living bodies in the course of operation and found spirochetes in twenty-five of the former and in fifteen of the latter. The results are set forth in the accompanying tables.

The spirochetes in the kidney were found mostly in hyaline casts, hyaline clots and also in the granular substance of the cortex, but not so many were found in the medullary substance. We have also noticed two cases of hyaline clots in Bowman's capsule, and two cases of homogeneous and granular casts in congenitally cystic kidneys. In contracted kidneys, we found spirochetes in the so-called cysts of retention. The location of the spirochetes in the casts of the urinary tubules was not always constant. In the same cases, we occasionally found only hyaline clots, but no other clots, and in from ten to twenty preparations we also found a few of them.

* In this column, ♂ denotes male and ♀ female.

The spirochetes we found we stained a deep black, according to Levaditi's method. They formed delicate spiral curved organisms, their average length being from 6 to 10 microns. The smaller forms were from 4 to 5 microns in length. Organisms 22 microns long have been observed, both ends of which are pointed. Morphologically, they may be divided into three types. Type I is much like the *Spirochaeta pallida*, particularly in its spiral form. Type II shows an irregularly curved spiral, while Type III is much broader than Type I or II, and its curves are much coarser and less regular.

What is the origin of our spiral bodies? If they were true spirochetes, they could be determined only by more minute examination, namely, by dark field illumination as living bodies and by Giemsa's staining as final objects. Our examinations, however, have not yet given satisfactory results. Occasionally we have noticed brown-stained irregular spiral forms in the silver-stained preparation, but it cannot be said that the mere finding of spiral forms is an evidence of the presence of true spirochetes. The presence of the spiral bodies in question which were morphologically difficult to differentiate from true spirochetes, without being related to any definite disease, is a very important fact.

In 1912 Le Play, Sézary and Vallery-Radot[1] found spirochetes in the kidney. Their report is very interesting, as the spirochetes they found seem to resemble our spirochetes. Le Play examined the kidneys in question according to Belltali and Vorpino's method and found black-stained filament bodies in the casts and exudate of the excretory and secretory ducts in cases of tuberculosis, arteriosclerosis, and lead intoxication associated with acute or chronic nephritis. There were, however, absolutely no suspicious signs of any syphilitic changes in the history of the case, nor in the Wassermann reaction, nor at the necropsy. The filament bodies much resembled *Spirochaeta pallida* and were found mostly isolated or else in groups in the cortical substance, but they were not found at all in the interstitial tissue, glomeruli or blood vessels. They were named *Pseudotreponema*. They were very much like the *Spirochaeta pallida* found in the urine of syphilitic patients, as reported by Hirschberg, McLennan, Dreyer and Toepel, and Barth and Michant; also in syphilitic kidneys, as reported by Le Play and Sézary, and by Faroy. For this reason, Le Play said that attention must be paid to spiral bodies in the urine and the kidneys. Ours and Le Play's spirochetes very much resemble one another and cannot be found elsewhere. It is difficult to assert, therefore, that the spirochetes found in the urine or in the renal casts are the specific causative agents in definite diseases and also in other spirochetal diseases. By means of dark field illumination and Giemsa's staining method, we examined centrifugalized casts in the urine of several nephritic patients and experimental nephritic animals, but none of the observations brought any satisfactory results.

SUMMARY

1. By Levaditi's method we have found many spirochetes in the hyaline casts and hyaline substances in urinary tubules, without relation to any diseases. Further and more minute attention must therefore be paid to the study of spirochetes in the kidneys.
2. Our spirochetes are found not only in the casts, but also in the hyaline or granular substances located in the cortical substances, in urinary tubules, in Bowman's capsule, and in cysts. But they have not yet been found in the blood vessels, in the interstitial tissues, or in the cells.
3. Our spirochetes may be divided into three types.

Obligation to Care for the Child.—The war cloud dims our vision of the facts at home. But in war or peace, there is this constant struggle for a living and a life. Today it is the mother in her distress that needs help and care; tomorrow it is the infant new-born; the third day it is the talking and walking child. For, whenever the one or the other is found, the tale of inadequate service, of danger, of damage, of disease and death is nearly the same, varying a little in local color but never in substance.—Dr. Leslie Mackenzie, Report on Scotland to Carnegie United Kingdom Trust.

Clinical Notes, Suggestions, and New Instruments

REPORT OF A CASE OF GONOCOCCIC ENDOCARDITIS

H. A. Benson, M.D., Camp Pike,
Little Rock, Ark.
First Lieutenant, M. R. C., U. S. Army

The rare occurrence and the difficulty of establishing the diagnosis would seem to warrant the reporting of this case of gonorrheal endocarditis.

History.—Private F., aged 19, admitted to the medical service of the Post Hospital, Plattsburg Barracks, N. Y., Sept. 19, 1917, complained of frequency of urination accompanied by a sense of burning, dull pain in the lumbar region, painful erections, and a profuse, purulent urethral discharge. The patient gave a definite history of exposure seven days prior to admission, and stated that he did not report for the regulation venereal prophylactic treatment. The fourth day after exposure he noticed a swelling of the meatus urinarius, and experienced a stinging sensation on urination. The following day the pain grew worse, and milking of the penis revealed a drop of mucopurulent discharge. Subsequently the discharge became more profuse and purulent, and chordee developed, which established clinically the outward picture of acute gonorrhea. The previous medical history was negative.

Physical Examination.—There was a profuse, purulent urethral discharge. The penis was swollen and tender. The testicles were apparently normal. Examination of the heart, lungs and joints revealed no external evidence of the infection. Urinalysis revealed a large amount of albumin, and an abundance of leukocytes. A smear of the discharge stained by Gram's method showed many polymorphonuclears, several of which were crowded full, some even bursting, with definite gram-negative, biscuit-shaped diplococci. Very few extracellular organisms were observed. A planting of the discharge was made to a plate of 5 per cent. glucose-agar enriched with one part in ten of ascitic fluid; and a second planting was made to a plate of starch-agar prepared according to Vedder's formula.[1] The blood pressure was normal. A leukocytic count gave 13,800 leukocytes, with 74 per cent. polymorphonuclear neutrophils. A specimen of blood was taken for the gonococcic complement fixation test, which at a subsequent date was reported positive.

Clinical Progress.—The usual clinical course showed no interruptions, the discharge continuing for several days. Smears stained by Gram's method still showed the presence of gram-negative intracellular diplococci. The other symptoms gradually subsided, the leukocyte count and the temperature returning to normal. The patient was up and about the ward for two or three days when he began to complain of pain in the right ankle, with swelling and tenderness, which later became so severe that he was again put to bed. There was a slight rise of temperature, and the leukocyte count increased to 14,000. The symptoms grew rapidly worse; the periarticular tissues becoming swollen and edematous, and there were pain and tenderness, marked redness, and impairment of function. The intense redness and extreme sensitiveness of acute articular rheumatism, however, were not present. There were no sweats; the temperature ranged between 99 and 102 F., the pulse averaged 80 per minute, and the respirations were practically normal. Urinalysis at this time revealed gonorrheal shreds, a trace of albumin, a few white blood cells, hyaline casts, and squamous and round celled epitheliums. The clinical symptoms continued in the ankle three days and began to subside, only to reappear, however, with equal severity. a few days later in the right elbow. At no time was there any effusion in the joint, and after the disappearance of the pain and swelling, there remained no evidence of former involvement. The clinical picture of the condition at the elbow was similar in all respects to the one at the ankle; and the migratory character of the disease was shown in the subsequent involvement of the right shoulder, right wrist and left knee. October 10, ten days after the patient had taken to his bed with arthritis, he had a slight chill which was followed by a sudden rise of temperature, weakness and dyspnea, and some precordial discomfort. Examination of the heart elicited a faint blowing systolic murmur at the apex. The pulse was arrhythmic, soft, compressible, and showed no dichrotism. A count of the white cells gave 17,000, with 78 per cent. polymorphonuclears. A smear from the urethra still showed a few gram-negative diplococci. The symptoms referable to the knee joint, though less severe, still persisted. The progress of the case showed slight fluctuations, but nothing eventful for a period of ten days. A comparison of the former cardiac findings with the present demonstrated a marked loss of muscle tonus, the booming quality of the first sound being replaced by a feeble, irregular cardiac pulsation. The characteristic variations of the murmur were well marked. At no time was the temperature above 103 F. Blood count revealed a polymorphonuclear leukocytosis. Blood culture was negative. The urine contained pus and an increased amount of albumin. During the next few days the patient improved slightly, but this proved to be only temporary, as he soon lapsed into his former state, the temperature increasing to 103.8 F., the respirations becoming shallow and increased in frequency, and the pulse rapid, irregular and easily compressible. The cardiac sounds grew more feeble and distant, and the murmur was at times inaudible. He grew progressively worse during the following forty-eight hours, expectorated frothy sputum, became orthopneic and profoundly toxic, and died.

Treatment.—At first remedial measures were directed toward the clearing up of the urethral discharge. Later the arthritis was combated by the use of polyvalent gonococcic vaccine (Army Medical School) beginning with 0.5 c.c. as an initial dose and increasing to 1 c.c. given at four day intervals for five doses. Later, on the theory of the nonspecificity of proteins, triple typhoid was substituted. Hexamethylenamin and salicylates were administered in appropriate doses, and a course of hydrotherapy followed. Despite the recognized cardiac therapy, the termination of the case was inevitable.

Laboratory Findings.—After twenty-four hours' incubation at 37.5 C., the glucose-ascitic-agar, and starch-agar plates were examined and the most suggestive looking colonies picked and transferred to tubes of blood agar, and Vedder's starch medium. Similar colonies were picked and stained and found to contain biscuit-shaped gram-negative diplococci. The following day the tubes were examined, and those found to contain only the gonococcus-like organisms in pure culture were used as a stock culture from which to make subsequent study. The cultural characteristics exhibited by this organism, as it was carried through the various mediums, were apparently morphologically identical with the gonococcus. Necropsy being refused, a few cubic centimeters of the heart's blood were aspirated and plantings made to the mediums mentioned above. After twenty-four hours' incubation, the suggestive colonies that appeared on the surface of the mediums were carefully studied by carrying them through the various mediums, and were found to correspond identically with the organism isolated from the urethral discharge.

Return Cases of Diphtheria.—J. Langer recently analyzed in the *Jahrbuch für Kinderheilkunde* the experiences with 7,701 cases of diphtheria in recent years at the Graz and Prague hospitals. There were ninety-seven return cases, a total of 1.5 per cent. The children were kept in the hospital until the secretions of nose and throat gave negative findings on one or more examinations. The persisting carriers, he states, should be isolated in a convalescent home and the throat and nose treated with pyocyanase, sodium sozoiodate, hydrogen dioxid, etc. This same treatment should be applied to the persons in the environment of a case, as in his experience, from 6 to 10 per cent. of the contacts harbored the bacilli. His article is summarized in the *Correspondenz-Blatt.*

Military Medicine and Surgery

A ROENTGEN STUDY OF ONE THOUSAND CHESTS, AT CAMP DEVENS, MASS.

E. L. DAVIS, M.D. (Springfield, Mass.)
Major, M. R. C., U. S. Army
CAMP DEVENS, AYER, MASS.

During the six months from Oct. 12, 1917, to April 19, 1918, more than 1,000 chests have been examined roentgenologically in the roentgen-ray laboratory at Camp Devens, Mass. The findings in these cases have proved interesting enough to warrant summarization, and it is my purpose in this paper to give an account of the study. Some phases of the roentgen interpretation of pulmonary disorders here presented are not new, and the material presented is merely corroborative. Some of the phases, however, are practically new, and the ideas expressed are based on material previously not available. Where generalities seem to have been drawn without sufficient substantiation, I hope to establish and extend these conclusions by further and more detailed study.

The patients dealt with in this study are men between the ages of 21 and 30 — officers and enlisted men of the Army. A few rare cases of officers above the age of 30 are included in this study. All these men had passed the preliminary examination of local physicians. They have been studied in our laboratory only on the request of medical officers in this camp either because of well defined lesions or because of suspected pulmonary disorder. Hence our statistics show a relatively small number of normal respiratory tracts.

In practically every case reported in this paper, the roentgen findings have been substantiated by the physical and clinical findings of examining surgeons. Daily consultation with the clinicians has assured me that the roentgen signs here described are definite and constant for the conditions to which they are ascribed. Doubtful cases have not been made a part of this discussion unless the uncertainty of interpretation has been distinctly pointed out.

Roentgenograms were made in every case here recorded, the roentgenoscope having been used for further study wherever necessary.

Pulmonary disorders have been found to occur as shown in Table 1. In this classification several cases in which complications occurred are tabulated under each of the conditions found. Hence the total number of cases is found to be somewhat greater than the total number of individuals examined.

TABLE 1.—OCCURRENCE OF PULMONARY DISORDERS

	No.
Individuals examined	1,259

Interlobar pleurisy	3
Pleurisy with effusion	25
Hydropneumothorax	3
Empyema	7
Emphysema	2
Enlarged mediastinal glands	1

TUBERCULOSIS

Pulmonary tuberculosis is demonstrable on the roentgenogram even in its earliest stages. Success in demonstrating the tuberculous lesion depends on the care in the technic and on the keenness of the interpreter.

The most definite signs of active pulmonary tuberculosis as seen on the roentgenogram are soft, fuzzy, flaky shadows in the areas occupied by the linear markings of the normal lungs. When these shadows are found at the periphery and are mottled as if broken up with shadows indicative of peribronchial thickening leading to them, we consider them characteristic of the acute, active tuberculous lesions. The soft shadows are interpreted as tubercles with areas of congestion about them, and the thickening of the trunks as lymphatics draining the infected area. Soft mottling in the apexes with peribronchial thickening leading to it we consider the most definite sign of active phthisis presented on the roentgenogram.

When, however, the shadows appear dense and are accompanied by nodular, well defined, clean cut peribronchial thickening which extends to the periphery, we consider them indicative of healed, or at least inactive, tuberculosis.

While these two extremes are readily detectable in the roentgenogram, it is often very difficult to interpret less marked cases. Often the shadows are appreciated only by well trained eyes, and much practice is necessary to give the examiner any degree of skill in the interpretation of tuberculosis in ill defined cases.

With regard to the relative frequency of occurrence of the tuberculous lesion, the lungs may conveniently be divided into three areas:

1. The upper region from the apex to the hilum is considered the tuberculous area. In this region by far the greatest number of infections are found. Ninety-three per cent. of the positive cases studied showed the lesion in this region; in 53 per cent. of these the lesion was in the right upper lobe; in 28 per cent. the lesion was found in the left upper lobe; in 11 per cent. there were lesions in both upper lobes.
2. The middle region from the hilum to the fifth rib in front is considered the intermediate region in which tuberculosis is occasionally found. Less than 10 per cent. of our positive cases showed tuberculosis in this region.
3. The lower region from the fifth rib to the diaphragm is considered the nontuberculous area where lesions are rarely found. Among all the 368 positive cases, only five showed shadows consistent with tuberculosis in the lower lobes. Two of these had lesions throughout all parts of both lungs; one had lesions in the upper, middle and lower lobes on the right side; one had lesions in the upper and lower lobes on both sides; one had a doubtful localized area of infection in the right lower lobe not verified by the clinicians.

Reference to Table 2 shows that more than half of the cases suspected of tuberculosis were found to be negative. In making an interpretation of normal lungs, it is appreciated that no lungs are absolutely free from some pathologic condition. The term is used to describe that condition on the roentgenogram consistent with shadows shown on plates made of individuals with no symptoms and with normal physical and physiologic signs. In some cases lesions were found in several regions of the lungs. For the sake of convenience in classification these are recorded separately in the table. For this reason the total number of instances recorded is greater than the actual number of cases.

I do not consider opacity in one of the apexes as compared with the other a significant factor in interpretation of pulmonary tuberculosis. This difference in opacity may be caused by a variation in penetrability on the two sides due to asymmetrical density of the sternomastoid muscles, to thickened pleura, or to a contracted apex.

Our study shows that hilum thickening cannot be considered a safe criterion on which to base a suspicion of pulmonary tuberculosis; for while an increase in the area and density of the hilum shadow may be very common in cases in which a definite pathologic condition is found, there are many cases which show marked thickening at the hilum with no signs of infection in the lungs. Seventy-nine of our cases showed marked ity in both hila with no evidence of tuberculosis the parenchyma of the lungs. This suggests the possibility that there is a good resistance to tuberculosis at the hilum and that these cases represent those in which the infection was inhibited at this place. The hilum resistance is emphasized by the fact that definite hilum tuberculosis was found in only four of the cases studied.

I am heartily in accord with the principle that pulmonary tuberculosis can be fairly and definitely diagnosed only with the combined consideration of clinical, physical and roentgen findings. There are instances, however, in which the roentgen signs are decisive even though physical signs are not found. Especially is this true in the cases of deep seated infections, and incipient tuberculosis in a part of the lungs other than the seat of the main invaded area. The fact that many tuberculous lesions are not found on physical examination, and that lesions are frequently larger in extent than determined by physical examination, would lead to the generalization that many cases of chronic fibroid tuberculosis give few or at least very indefinite signs on auscultation or percussion.

TABLE 2.—LOCATION OF TUBERCULOUS LESIONS

	No.	Per Cent.	
Cases examined for tuberculosis	773	....	
Practically normal lungs	326	....	
Hilum markedly thickened, but no signs of tuberculosis	79	....	
Total number of negative cases	405	....	
Total number of positive cases	368	....	
Tuberculosis, active, right upper lobe	121	31.9	53.2
Tuberculosis, inactive, right upper lobe	81	21.3	
Tuberculosis, active, left upper lobe	70	18.	28.5
Tuberculosis, inactive, left upper lobe	40	10.5	
Tuberculosis, active, both upper lobes	32	8.4	11.
Tuberculosis, inactive, both upper lobes	10	2.6	
Tuberculosis, active, right upper and middle lobes	6	1.6	
Tuberculosis, inactive, right upper and middle lobes	3	.79	
Tuberculosis, active, right middle lobe	4	1	
Tuberculosis, inactive, right middle lobe	2	.52	
Tuberculosis, active, right upper, middle and lower	1	.26	
Tuberculosis, active, both hila	2	.52	
Tuberculosis, active, left hilum	3	.79	
Tuberculosis, active, both lower lobes	1	.26	
Tuberculosis, active, all parts of lungs	2	.52	
Tuberculosis, doubtful, right lower lobe	1	.26	
Tuberculosis in upper area	366	93.	
Tuberculosis in middle area	23	6.	
Tuberculosis in lower area	5	1.	

The fan-shaped thickening of the ascending trunks as an indication of the tuberculous lesion has not proved helpful in our interpretation of tuberculosis. The roentgen picture of tuberculous lesions varies so much that it is not safe to describe it in any very definite manner.

In examining roentgenograms of pneumonia patients made shortly after resolution, shadows are seen which appear strikingly similar to those found in pulmonary tuberculosis. I believe that these shadows are caused by sheets of fibrin that are deposited on the pleura at the time of infection. Moreover, when the lobar pneumonia is complicated with a streptococcus infection, on the postpneumonia roentgenograms, along the ascending trunks and in the apexes, there appear shadows identical with those that occur in pulmonary tuberculosis. These gradually disappear and are not found after several weeks. It is important not to make the mistake of interpreting these shadows as tuberculous lesions, and in order to guard against the possibility of such an error the examiner should know definitely whether or not there is a history of recent pneumonia.

LOBAR PNEUMONIA

The roentgenogram has proved to be an important factor in the diagnosis of lobar pneumonia and in following its development. It has been found to be of extreme importance in differential diagnosis and in the detection of effusion. Consequently this study materialized when it was learned that the patients could be transported to the roentgen-ray laboratory without suffering the slightest ill effects. Application of the utmost care in handling the patients has made it possible to roentgenograph them without causing them mental or physical indisposition. Attending surgeons reported in all cases that no patient ever was found to have shown any ill effects resulting from the moving necessary to make the roentgenograms. The patients were placed on operating trucks, drawn to the laboratory through closed corridors, roentgenographed on the trucks, and returned to their wards immediately, the entire process covering not more than ten minutes.

Two hundred and fifty-eight cases of lobar pneumonia have been studied, and these encourage some very definite generalities. The roentgen signs of lobar pneumonia are: (1) marked accentuation of linear shadows from the hila to the apexes, which we propose to call vascular congestion; (2) marked enlargement of the heart shadow; (3) typical shadow of the localized area of consolidation in the lungs, and (4) high diaphragm on the affected side.

1. The vascular congestion appears especially in the upper lobes as soft linear markings with distinct bifurcations, which are different in appearance from the thickened ascending trunks of bronchitis and the peribronchial thickening of tuberculosis in being thicker, smoother, showing more definite branching, and being always definitely bilateral.

These shadows are interpreted as due to the congestion of blood vessels along the bronchi. They have the characteristic appearance of congested blood vessels, and depict what may be conveniently called an acute congestion of the lungs. These shadows also represent a thickening of the lymphatic vessels in increased drainage. The vascular congestion was found in all the 258 cases examined, excepting four, one a very early case not studied further, one a case of the abortive type quickly resolving, and two peculiar cases which showed neither the thickened ascending shadows nor the enlarged heart but only the area of consolidation, nontoxic cases.

The markings in question appear early in incipient pneumonia, and disappear early in resolution. They persist occasionally in cases in which no consolidation appears. In such instances these shadows persisting in the upper lobes and extending into the apexes are apt to be confused with the shadows indicative of tuberculosis. Their persistence sometimes for months makes their interpretation all the more confusing. Clinical history and repeated roentgenograms are valuable in these cases. However, in the majority of cases the shadows indicative of vascular congestion disappear early in resolution.

2. The heart is found to be enlarged both to the right and to the left. Only the right auricle, the left auricle and the left ventricle are distinguishable on the roentgenogram. Enlargement to the left is probably due to increase in size of the right ventricle overlapping the left ventricle, and the apical impulse is assumed to be that of the right ventricle rather than of the left ventricle, so that the enlargement to the left is due to the shadow cast by the right and left ventricles together.

The enlarged heart has been found in every case studied except two. These cases showed the area of consolidation in the lungs, but showed no enlargement of the heart and no vascular congestion, appearing to be cases in which there was only a slight degree of toxicity.

The heart enlarges early. The enlarged heart, with the vascular thickening, has been found in many of the cases before any signs of consolidation have appeared. It seems as though the toxins of the pneumococcus affect the myocardium definitely before localized manifestations in the lungs appear. Besides toxemia, the pulmonary consolidation and hyperpyrexia have been considered as causes of the enlarged heart. The early enlargement detected by the roentgenogram, however, seems to show that the toxemia is the most important factor in the enlargement of the heart.

It is possible that the enlarged heart occurs in other toxemias, though this has not yet been conclusively demonstrated. However, with vascular congestion in the upper lobes, this enlargement is a definite sign of beginning lobar pneumonia. This is clearly demonstrated in cases in which there are definite clinical signs of pneumonia, but in which no consolidation is found. In these cases the roentgen diagnosis is made on the two signs in question.

The cardiac enlargement persists for some time after the consolidation has cleared up and the patient has apparently recovered from the attack. This persistence varies with individuals. I am now making a study of the hearts of patients recuperating from pneumonia. The patients are examined at intervals of one week, and tracings of the heart shadow are made on glass with the roentgenoscope. These tracings, it is admitted, are not as accurate as the seven foot plates, but I believe that they are accurate enough for a study of the relative size at intervals of the same heart. Stature, size of chest, height and weight are factors considered in this study. It appears that the heart remains enlarged for several weeks (varying from four to eight weeks) after all evidence of definite involvement of the lungs has disappeared physically, clinically and roentgenographically. The patients are short of breath and show a rapid pulse with exertion as long as the heart is enlarged. In fact, this inconvenience to the patients when they were supposed to be fit for duty caused their return to the hospital and suggested this study. Clinically, these hearts give no evidence of valvular disease.

Weekly examinations of fifty such cases have been made extending over eight or ten weeks. It was found that in 50 per cent. of these cases the heart continued to enlarge slightly during the first, second and third weeks following discharge from the hospital, after which it gradually assumed its normal proportions. In the other 50 per cent. the heart was found to have decreased in size slightly each week until the normal size was reached, or to have remained unchanged in size for several weeks, finally diminishing gradually to the normal size. The unexpected increase in size of the already enlarged heart during convalescence was probably due to the fact that a strain was put on the heart too soon; but it has been impossible to secure satisfactory data on this point. None of these men were assigned to active duties during this time, but it is possible that they participated in exercises to an extent sufficiently strenuous to embarrass the already weakened cardiac muscles. There is now being developed at this camp a series of graduated exercises for recuperating pneumonia patients, the purposes of which are to strengthen these weakened hearts and to determine more definitely when the men are actually fit for vigorous duty.

3. Consolidation in the lung shows as a definitely localized homogeneous patch varying in density from complete opacity to transluscency. The consolidation may originate near the median line, in which event it may or may not extend to the periphery, or it may be found at the periphery not extending to the inner border of the lung.

The location of the consolidation in the 258 cases studied is summarized in Table 3. Of the 258 cases examined, thirty-one showed no consolidation in any part of the lungs, though the clinical symptoms were definite for lobar pneumonia, the crisis appearing early. No physical signs of consolidation were made out. In these cases the vascular thickening and the enlarged heart were found to be just as typical as in the cases with definite consolidation. Several examinations at intervals of two days showed that no consolidation ever appeared. These findings are in accordance with the idea that the symptoms of pneumonia are dependent more on toxemia than on the extent of pulmonary involvement.

TABLE 3.—LOCATION OF CONSOLIDATION

Area Involved	No.

Right middle and lower lobes	5
Right upper, middle and lower lobes	2
Left lower lobe	93
Left upper lobe	6
Left upper and lower lobes	2
Root of left lung	1
No consolidation	31

In several cases consolidation was shown roentgenographically before it was demonstrable by physical signs.

The extension of the consolidation from a small patch to a larger one and from one lobe to another was observed in several of our cases.

Several examinations of the same cases at intervals have led us to believe that the variation in amount of tissue involved in consolidation, and the change in location of the consolidated tissues, may be readily demonstrated roentgenographically.

During resolution, linear shadows are seen traversing the affected area and sometimes running beyond it. These are probably due to the thickening along the bronchi caused by some of the exudate, which has not absorbed, and has been transformed into dense, fibrous masses. These shadows may suggest the fibrosis of chronic tuberculosis. When they are found to have changed in position on several plates or when they finally clear up, it is safe to assume that no tuberculosis is indicated.

The question of cirrhosis of the lung in some of the cases of delayed resolution is now being studied in our laboratory. The evidence from cases thus far observed leads us to believe that cirrhosis of the lungs occurs in some cases.

4. The diaphragm on the affected side, as in other pulmonary disorders, is usually relatively higher than on the unaffected side. For some time the diaphragm on this side remains impaired in its excursion. In some cases after resolution the diaphragm appears irregular on the affected side, appearing to have a fixed point. Roentgenoscopically the diaphragm is fixed or else it has a limited excursion as compared with the nonpathologic side. In some cases, distinct bands of adhesions have been seen extending from the pleura to the diaphragm, limiting its motion.

That the elevation of the diaphragm cannot be used as a definite criterion for predicting the side in which consolidation is to occur has been clearly demonstrated by many of our cases in which the diaphragm was found to be relatively higher not on the affected side but on the unaffected side. The facts that in some of these cases the patients complained of pleurisy pain on the side opposite the consolidation, and that in three such cases the pneumonia was followed by a pleuritic effusion on the side opposite that in which consolidation occurred, encourage the suggestion that the high diaphragm on the side opposite the consolidation is an indication of pleurisy; but our statistics are too meager for a bold presentation of this position.

FLUID WITH LOBAR PNEUMONIA

In the presence of consolidation it is difficult to determine when fluid is present in sufficient amount to demand aspiration. The fluid does not appear the same on the roentgenogram as in pleurisy with effusion, when the patient is roentgenographed in the prone position. Instead of the typical S-shaped shadow found in simple pleurisy with effusion, the fluid in pneumonia seems to gravitate to the posterior part of the thorax, giving only a very faint shadow over the entire side, which may easily escape detection. This appears to be due to the fact that the portion of the lung solidified by the pneumonia makes compression of the lung impossible; and owing to the resistance offered by this mass, the fluid spreads out over the whole thorax. The difficulty thus presented has been obviated to some extent by making the roentgenogram with the patient in a semiupright position. The fluid then gravitates to the lower part of the chest and may be more readily seen. In case the fluid is purulent, as in empyema, reasonable time must be allowed for it to gravitate.

In our series of lobar pneumonia, pleuritic effusion occurred early in many cases, often by the second or third day. Thickened interlobar pleura is often seen and may be so dense as to suggest fluid between the lobes.

BRONCHOPNEUMONIA

It has been quite generally supposed that bronchopneumonia is a bilateral disease. Our study has shown that it is more commonly unilateral. This is shown by reference to Table 4.

Signs of vascular congestion in the upper lobes are not so marked and certainly not so constant as in lobar pneumonia.

The heart is sometimes slightly enlarged, but never to the extent found in lobar pneumonia, and often not at all.

The localized area of consolidation appears more as a mottling than as a homogeneous shadow as in lobar pneumonia. Figuratively, the picture of the infected area in bronchopneumonia seems to have been smeared on the plate with a worn-out brush, while in lobar pneumonia the area of consolidation seems to have been blown on the plate with an atomizer.

The pleura does not seem to be involved in bronchopneumonia nearly as much as in lobar; a thickened pleura is seldom seen.

TABLE 4.—LOCATION OF BRONCHOPNEUMONIA

	No.
Cases observed	61
Bronchopneumonia, both lower lobes	20
Bronchopneumonia, right lower lobe	27
Bronchopneumonia, left lower lobe	14

Several peculiar cases of bronchopneumonia were discovered in the course of this study. The patients, most of them officers, were not indisposed enough to take advantage of a ward bed, but were troubled with a persistent cough, weakness, and slight elevation of temperature. The roentgenograms revealed that these were typical cases of bronchopneumonia, the majority of which were localized in one or both of the lower lobes. Resolution in these cases was slow, the shadows persisting for several weeks.

SUMMARY

I. Pulmonary Tuberculosis:

1. Pulmonary tuberculosis is demonstrable on the roentgenogram even in its earliest stages. It is difficult to describe concisely the appearance of shadows that will enable the roentgenologist definitely to interpret active and inactive tuberculosis. One can only describe what in general is seen in well defined cases. The specialist instinctively learns to detect these shadows by individual methods.

2. The lungs may be divided into three regions with regard to the occurrence of pulmonary tuberculosis: the upper region, in which tuberculosis is commonly found; the middle region, in which tuberculosis is sometimes found, and the lower region, in which tuberculosis is rarely found.

3. Consultation with conscientious clinicians has led to the conclusion that many cases of chronic fibroid tuberculosis give very indefinite, if any, physical signs.

II. Lobar Pneumonia:

1. Lobar pneumonia and bronchopneumonia are easily distinguishable on the roentgenogram.

2. Lobar pneumonia gives the following roentgen signs:

(1). Vascular-lymphatic congestion in the upper lobes.

(2). Enlarged heart.

(3). Localized consolidation.

(4). High diaphragm.

3. Vascular-lymphatic thickening appears early and disappears early, though its occasional persistence may be confused with tuberculosis shadows.

4. Pneumococcemia shows definitely on the roentgenogram when there are symptoms of pneumonia without consolidation, suggesting that the seriousness of the attack depends more on the toxemia than on the extent of pulmonary involvement.

5. The heart is involved before definite signs of consolidation appear.

6. The cardiac enlargement persists for some time after all signs of involvement of the lungs have disappeared.

7. Consolidation may begin at the roots or at the periphery.

8. High diaphragm on the affected side is suggestive, but cannot be considered a constant sign.

III. Bronchopneumonia:

1. Bronchopneumonia is more commonly unilateral than bilateral.

2. The heart is usually not enlarged in bronchopneumonia.

3. Bronchopneumonia is often overlooked on physical examination, as the symptoms may be indefinite and noncharacteristic.

A BACTERIOLOGIC STUDY OF THE PNEUMONIA OCCURRING AT CAMP PIKE, ARK.

GEORGE F. DICK, M.D. (Chicago)
CAMP PIKE, LITTLE ROCK, ARK.

Pneumonia has been one of the important diseases encountered at the base hospital since the opening of Camp Pike. Table 1 represents the results of bacteriologic examinations of the sputums obtained from sixty patients admitted to the hospital during the months of February and March. The sputum was collected from the patients in sterile Petri plates and sent to the laboratory at once and plated on the surface of human blood agar plates without addition of glucose. The table shows the predominant organisms that developed on the plates and most of the other organisms found after forty-eight hours' incubation, along with the clinical types of the disease with which the bacteria were associated.

The importance of the bacteria predominating in these sputums was substantiated in a number of cases by bacteriologic examinations of the blood during life and of the lungs after death.

From the table it will be seen that pneumococcus pneumonias present but little out of the ordinary. It will be seen that two of the Type II cases were complicated by severe jaundice. Since these data were collected, a number of similar cases have been observed, and as in the two above, all were in colored persons, some of whom were known to have syphilis and one multiple gummas of the liver. The pneumococcus cases form 48 per cent. of the sixty cases in this series. Of these, 21 per cent. were Type I, 34 per cent. Type II and 45 per cent. Type IV. I have seen only one Type III case in the hospital.

In 46 per cent. of the cases, streptococci were the predominating organisms; of these, 46 per cent. were nonhemolytic. These organisms formed colonies similar to the hemolytic streptococci, but had no effect on blood, neither hemolysis nor green formation being observed. The organisms were like the hemolytic streptococci as to morphology, but had more tendency to diplococcus formation, and the chains formed were short. Growth in both was flocculent and collected in the bottom of the broth. In the cases coming to necropsy the pneumonia in which this type of organisms was found resembled the ordinary pneumococcus lobar pneumonia. This type of streptococcus was found in the sputum in two cases diagnosed as influenza, and in the pus from a gangrenous appendix, in greatly predominating numbers.

Fifty-four per cent. of the streptococci found were hemolytic. The lesions found at necropsy in these

Pneumococcus	48%	Streptococcus	46%
Type I	21%	Hemolytic	54%
Type II	34%	Nonhemolytic	46%
Type IV	45%	Leptothrix	6%

cases were of two kinds: 1. A pneumonia similar to lobar pneumonia due to pneumococci, but with a tendency to pus formation. In many cases this was not more marked than that sometimes observed in the pneumococcus cases in others. Abscesses with areas of necrosis varied in extent, sometimes amounting to gangrene of large portions of the lung. 2. Bronchopneumonia in which the lungs were studded with hard, shotlike nodules, which were extremely hard to the palpating fingers. Cut sections of such lung showed areas up to 1 cm. in diameter which were dark red and completely consolidated. This form was most commonly observed following measles. The areas in some instances coalesced to form areas, in cases amounting to a lobe. In twenty-five of a series of thirty cases of mastoiditis, streptococci indistinguishable from these were isolated. The remaining five were Type IV pneumococcus infections.

TABLE 2.—FERMENTATION CHARACTERISTICS OF HEMOLYTIC AND NONHEMOLYTIC STREPTOCOCCI

Organisms	Effect on					
	Milk	Salicin	Raffinose	Inulin	Mannite	Maltose
1. Nonhemolytic streptococcus from sputum in lobar pneumonia....	—	—	—	—	—	—
2. Nonhemolytic streptococcus from appendix	—	—	—	—	—	—
3. Nonhemolytic streptococcus from lobar pneumonia	—	—	—	—	—	—
4. Nonhemolytic streptococcus from lobar pneumonia	—	—	—	—	—	—
5. Nonhemolytic streptococcus isolated from "influenza".........	—	—	—	—	—	—
6. Hemolytic streptococcus isolated from influenza	Acid	—	—	—	—	Acid
7. Hemolytic streptococcus isolated from lobar pneumonia.........	Acid	—	—	—	—	—
8. Hemolytic streptococcus, bronchopneumonia	Acid	—	—	—	Acid	Acid
9. Hemolytic streptococcus, bronchopneumonia	Acid	Acid	—	—	Acid	Acid
10. Hemolytic streptococcus, bronchopneumonia	—	Acid	—	—	—	—
11. Hemolytic streptococcus, postmeasles bronchopneumonia	Acid	—	—	—	—	Acid
12. Hemolytic streptococcus from mastoid	Acid	—	—	—	Acid	Acid
13. Hemolytic streptococcus from mastoid	Acid and coag.	Acid	—	—	Acid	Acid
14. Hemolytic streptococcus from mastoid	Acid	—	—	—	—	Acid

Both the types of streptococci were more frequently complicated by empyema than were the pneumococcus cases. In the hemolytic cases in two instances there was peritonitis.

The fermentation characteristics of the two types of streptococci are shown in Table 2.

Leptothrix organisms predominated on the plates in 6 per cent. of the cases. These were very minute colonies, barely visible to the naked eye, but extremely numerous. There was no effect on blood. The organisms were gram negative, and varied in length from organisms resembling influenza bacilli to long, slightly wavy organisms extending half way across the field. It was not possible to cultivate these organisms beyond one or two subcultures, and their importance is undetermined.

The series is interesting on account of the high percentage of streptococcus infections, particularly those due to nonhemolytic organisms, which were also found associated with cases diagnosed as influenza and in the pus from appendicitis.

PRIMARY AND DELAYED PRIMARY SUTURE IN THE TREATMENT OF WAR FRACTURES

WILLIAM S. BAER, M.D. (Baltimore)
Major, M. R. C., U. S. Army; Assistant Director of Orthopedic Surgery, A. E. F.
FRANCE

The treatment of fractures from battle casualties is for the most part the treatment of wounds of the soft parts, plus the added difficulties which the injuries to bony tissue involve.

To understand, therefore, the treatment of fractures, one must thoroughly appreciate the changes which have been made in the treatment of wounds of the soft parts.

American surgery is most fortunate in arriving on the scene when the principles of war surgery have been established. The biblical truths, as laid down by our French and English colleagues, have been founded on no uncertain grounds and have been enunciated in no uncertain terms.

These principles may be stated in this manner:

1. All battle wounds are to be considered as infected.
2. It is necessary to remove all projectiles, clothing and devitalized tissue as early as possible, at least before the twelfth hour after injury.
3. These wounds can then be considered as aseptic in character and a primary suture made, thus converting compound fractures into simple fractures, and appropriate treatment for these simple fractures thereupon instituted.

What a marvelous and astounding change is this in the application of surgical principles since that fatal day in August, 1914. One cannot but stand in awe and wonder at the results that have been achieved as one compares the past with the present: pus, contrasted with a clean lineal scar; continued pain caused by the packing of gauze and constant irrigation, with the peace of being left alone; the long and often painful processes in the restoration to function, with function restored almost voluntarily and swiftly; weeks and months of treatment, with recovery in a comparatively short time.

I say we are most fortunate as surgeons in coming into the war at such a period; the hard and costly lessons have been learned by the suffering of our allies. We shall be held responsible, and rightly so, if we do not appropriate and practice that which has been laid down for us by the work and at the expense of others.

How have these things come about? By the formation of a trust—a trust composed of the surgeon, the bacteriologist and the roentgenologist, all working harmoniously and constantly together.

Roentgenology.—Every man wounded in battle is roentgenographed immediately on entrance to the hospital, and, generally, while en route to the operating room. A definite description of the fracture is given, and, if a projectile is present, its exact location is made, generally by means of fluoroscopy. These localizations are generally indicated on the surface, by two markings, and the distance and direction from each marking is stated.

Bacteriology.—The bacteriologist determines for us the type of organisms present in the wound. Ninety per cent. of all these wounds are found to be infected by one or more organisms. Here we have both aerobes and anaerobes; the types most commonly found are the stayphylococcus, the streptococcus, the pneumococcus, the colon group and the organisms producing gas gangrene. We have learned from these bacteriologic studies just what course we may pursue in our operative treatment, just what conditions will prevent a successful primary closure, when it will be necessary immediately to open a wound primarily closed, what the indications are for a secondary closure and how soon it may be done (Carrel), etc.

Surgery.—The surgeon in the first place must be a surgeon of the highest character, for he must perform aseptic surgery in a supposedly septic field or at least in a field which has the potentialities of sepsis; his dissections must be clean, his handling of tissues of the minimum, his knowledge of anatomic structures accurate.

I. PRIMARY SUTURES

The primary suture is the method of selection when this can be done. Experience has shown that primary suture may be successfully performed in from 80 to 95 per cent. of the cases. It is obvious that in certain cases primary suture cannot be done, owing to the inability to make a closure, because of the destruction of large amounts of tissue, including skin. But even here the primary suture at times may be accomplished by the aid of a skin flap.

Technic of Primary Suture.—The skin is disinfected with iodin, soap, water and a scrubbing or other methods. The skin edge, together with the tract made by the projectile, is removed. All projectiles and *all* devitalized tissue are removed. Complete hemostasis is performed. The skin edge is accurately approximated without tension.

Results of Primary Suture.—As has been said, primary suture may be done in from 80 to 95 per cent. of all battle casualties, if operation is performed within a proper time. This is generally regarded as within the first twelve hours; but in face cases, the time limit for successful primary suture is slightly increased. According to Lemetre, from July, 1915, to February, 1918, he had performed 2,664 primary sutures with complete success in 2,549 cases, or 95 per cent., partial failure in eighty-three cases, or 3.1 per cent., and complete failure in thirty-two cases, or 1.2 per cent.

The ordinary surgeon would consider these partial failures to be complete cures, for they were stitch abscesses which granulated in a few days and did not affect the deep structures or interfere with the integrity of the wound.

Duval says that in periods of calm at the front, when the patients are received in proper time, 90 per cent. of the wounds can be closed by primary suture; but in times of stress only 30 per cent. may be sutured primarily, delayed primary suture being its substitute.

In cases in which primary suture is done, 95 per cent. are successful. According to Gross, of 759 wounds treated by primary suture, 88.8 per cent. were successful. Thus I might go on giving the results of others' work. So we see that in the hands of good surgeons at the front, when the wounds are received within from eight to twelve hours after the casualty, roughly speaking, from 80 to 95 per cent. of all such wounds, of whatever nature, soft parts or bone, can be treated successfully by primary suture, and, of these primary sutures, from 90 to 95 per cent. are successful.

Advantages of Primary Suture over Other Methods of Wound Treatment.—1. The mortality is greatly decreased, primarily because there is escape from the grave danger of secondary infection, so frequent when the wound is left open. In witness of this fact, the statistics of the hospitals of the interior in France in open wounds show a streptococcus infection of 80 per cent., whereas in fresh wounds from battle casualties there is only a 10 per cent. infection of this nature.

2. The patients suffer less, as they escape the necessity of all secondary and continuous dressings.

3. By primary suture the restoration of function is obtained more quickly and more completely, as there is no amount of scar tissue, or dense adhesions of muscles, tendons and joints, as is so frequently the case when wounds heal by granulation.

4. The period of hospitalization is therefore wonderfully decreased, which is of primary importance from a military point of view.

5. The amount of dressings necessary for the treatment of the wounds is likewise decreased in a marvelous degree, the importance of which cannot be overestimated in a war whose base of supplies is so many miles away.

6. In like proportion, compound, infected fractures are changed into aseptic, simple fractures, and may be treated as such,

It has been said that 10 per cent. of battle wounds, even when the wounded men have arrived at the hospital within the first twelve hours, cannot be primarily closed, mainly in these instances: cases in which the shock is so great that the patients cannot stand the operation within the first twelve hours; deep wounds in which the complete excision of all devitalized tissue is uncertain or impossible; wounds in which no roentgen apparatus being present, the projectile cannot be extracted, and wounds in which the loss of substance is so great that complete closure is impossible. It has been shown that from 5 to 10 per cent. of the primary sutures are not successful, and this is due mainly to the streptococcus.

In an evacuation hospital, all wounds that are seen within the proper time after injury, which are applicable to primary suture, are closed by this method. At the same time, cultures of the wounds are taken. The wounds that must be opened immediately on the bacteriologic report are those primarly infected with the virulent types of streptococci. A bacteriologic report of other organisms does not in the main disturb us.

We know that the mechanical sterilization by the operative procedure of primary suture, together with the action of the human tissue, take care of all other organisms, particularly when in pure culture. The virulent streptococci generally by themselves, and always when associated with other organisms, such as the streptococcus, enterococcus, the gas gangrene group, etc., demand immediate opening of the primary suture.

II. DELAYED PRIMARY SUTURES

The delayed primary suture is the method of wound closure that has been adopted in all those cases in which primary suture would have been done, except for circumstances, generally of military character, that made it inadvisable. The technic of delayed primary suture is exactly that of primary suture, except that the skin is not closed, and a dry sterile dressing is placed over the wound. The skin edge is brought together from three to eleven days later.

A hospital at the front can generally in times of stress keep only 20 per cent. of its beds permanently filled. All patients with primary sutures should be kept at the place of operation for at least ten days, so that the wound may be watched and not subjected to the traumatism in transportation. Therefore, when patients must be removed immediately, within six or seven hours after operation, delayed primary suture takes the place of primary suture.

This method of procedure has been found eminently successful. Patients with delayed primary sutures are sent to the rear within six or seven hours after the initial operation, and the wounds are closed preferably on the second, third or fourth day. The percentage of cures in delayed primary sutures is between 80 and 87. This method allows the beds at the front to be continuously utilized, and adds to the rapidity of recovery over the former methods, according to the statistics of Duval. By delayed primary suture, 32 per cent. of the patients were returned to duty in three weeks, 30 per cent in one month, and 28 per cent. in two or more months.

III. FRACTURES

My particular object is to emphasize the necessity for the early treatment of bone injuries, by primary or delayed primary suture, for this is the keynote to the successful handling of war fractures. To change an infected compound fracture into an aseptic, simple fracture at the outset, is to do away with the greatest difficulties that are found in the treatment of war fractures. It is not my intention to take up the mechanical principle on which fractures, generally compound, of the various bones of the body are to be treated. That is well set forth in the Splint Manual, authorized by the American Expeditionary Forces; but I wish to insist that, by the use of the principles of primary and delayed primary suture, the entire subject of the treatment of fractures has been changed; that one is no longer treating compound fractures with all the difficulties thereunto appertaining, but has the much simpler task of the treatment of a simple fracture.

The reader may interpose to say that the statistics I have given are those appertaining only to soft part wounds, and the infection of bones is another and far more difficult proposition. That is not the case; the figures given are taken from the injuries to bones as well as of the soft parts. Indeed, the infection of bones is generally secondary to the infection of soft parts. Therefore it follows that, if by primary or delayed primary suture this infection can be stopped or removed, the bone will not become infected.

In the statistics given by Lemetre (Table 1), in a series of 421 compound fractures of all bones, among which there are fifty-one compound fractures of the humerus and twenty-six of the femur, the most difficult of all war wounds to treat and the ones which formerly gave the highest mortality, there is a complete cure with a simple fracture of 91 per cent.; and, if we add the partial failures which do not affect the treatment of the fractures, we have 97 per cent. of cures, better than that for soft part wounds.

Again, according to Gross (Table 2), there were 213 infected compound fractures treated by primary suture. These were changed into aseptic simple fractures in 89 per cent. of the cases; and so I might quote other authorities whose statistics bear out these wonderful results.

TABLE 2.—PRIMARY SUTURES OF BONE FRACTURES (GROSS)

Leg: Tibia	19	13	2	4
Leg: Fibula	6	..	1	5
Tarsus, Metatarsus	14	..	..	..

The rules of the game have, therefore, been laid out for use by the application of this scientific knowledge, by combination of the surgeon, the roentgenologist and the bacteriologist. As Médecin-Principal Duguet has said, "Thus the old formula which subordinates the surgical act to the preestablished sanitary formation finds itself reversed." Today, it is the sanitary organization in its entirety that conforms and adapts itself to the exigencies of modern surgical technic. All compound fractures must be operated on by the technic of primary or delayed primary suture, within eight or ten hours of the casualty. Thus the problem is one of the treatment of the simple fracture.

The transportation of the wounded must be accomplished with this end in view. Hospitals of sufficient size must be located in the zone of the advance near enough to make this transportation possible.

Each hospital must be adequately staffed with surgeons of sufficient skill, with a bacteriologist and roentgenologist, in constant consultation for the proper carrying out of this technic.

INFLUENZAL SINUS DISEASE AND ITS RELATION TO EPIDEMIC INFLUENZA *

H. E. ROBERTSON, M.D. (Minneapolis)
Major, M. R. C., U. S. Army
FRANCE

A typical attack of influenza usually begins as a rhinitis and spreads from the nasal mucosa throughout the respiratory tract. As the chief symptoms are produced by the involvement of the bronchial tree, attention is naturally directed to the lungs and bronchi as the most important foci for the infection. However, in studying acute cases one is often impressed by the fact that the severity of the disease, best evidenced by the general prostration of the patient, is out of all proportion to the physical signs. Tracheobronchitis with abundant mucopurulent sputum, a particularly distressing and often spasmodic cough, and moist râles uniformly present in both lungs, almost exhaust the positive findings for the respiratory tract. It becomes difficult to understand why a vigorous, previously healthy young adult, should succumb to an infection which in many cases appears to be almost wholly confined to the tracheobronchial mucosae. It might even be questioned whether such an individual should die from a *primary* bronchitis and bronchopneumonia. In the opinion of many clinicians and pathologists, such a combination is rather rare.

Because of these considerations and because of a series of observations made on soldiers of the American Expeditionary Forces, it has seemed desirable to suggest that in addition to the infection of the respiratory tract per se, other lesions, almost uniformly neglected by writers on the subject and rarely noted by clinicians or pathologists, may prove to be very seriously important factors both in the clinical picture and in the often fatal outcome of the disease.

My attention was first directed to the serious nature of so-called "influenzal purulent bronchitis," by a visit in October, 1917, to the base hospital zone of the British Expeditionary Forces in France, at which time Captain Rolland of the Royal Army Medical Corps mentioned his observations in a series of cases of this disease, which had occurred in epidemic proportions and which was highly fatal. The influenza bacillus seemed without doubt to be the causal agent, though pneumococci and streptococci were often also isolated.

On the advent of cold, wet weather in the American Army zone, severe attacks of bronchitis assumed almost the nature of an epidemic and showed a rather high percentage of fatal cases. On examination of these cases postmortem, one was at once struck by the pathologic syndrome presented, which strongly suggested infection by *B. influenzae*. This suspicion was subsequently confirmed by bacteriologic examination.[1]

It is not my purpose at this time to discuss either the general pathologic or bacteriologic characters of this series of cases. It is the involvement of the sinuses at the base of the skull that deserves especial consideration, and because of the importance of this complication, as well as its apparent frequency and the relatively small amount of attention devoted to the subject in medical literature, this separate communication is considered justifiable.

Infection of the accessory sinuses of the nose and skull have often been noted. As early as 1837, Petrequin[2] stated that frontal sinus involvement produced the headache so often present in the disease. Brochin,[3] in 1884, distinguished the "cephalic" form of influenza by localizations in the nasal fossae, and the frontal and maxillary sinuses. Pfeiffer,[4] however, in his classic descriptions of the etiology and pathology of influenza, does not mention the sinuses. In the same year (1892), Weichselbaum[5] published the necropsy findings of a series of cases, in six of which he found inflammatory lesions in either the ethmoids or the antrum. In two of these cases the influenza bacillus was recovered from the exudate. Bull[6] has also described sinus involvement as a part of the sequelae of influenza. Wassermann,[7] in a fairly complete study of clinical cases and necropsy material, while confirming Pfeiffer's results, evidently did not encounter or missed the significance of any sinus complications. In a review of the entire subject of influenza, Schrötter[8] also fails to note the relation of the sinuses to pulmonary types of the disease.

In the more recent literature there are occasional references to sinus influenza, notably by Kyle[9] and Coates;[10] but Hübschmann,[11] in a study of 110 cases, and Hammond, Rolland and Shore,[12] in an article based on seventy-one necropsies on patients showing purulent bronchitis, do not discuss at all the question of the sinuses. In short, sinus disease in epidemics of influenza is either totally disregarded or described as an accidental complication or sequela of the infection of the pulmonary tract.

When, therefore, our first fatal case of influenzal tracheobronchitis and bronchopneumonia showed, at postmortem examination, an empyema of both sphenoid cavities, and the pus from these revealed by both smears and cultures typical influenza bacilli, the condition was regarded as an interesting but unusual complication. However, as case after case coming to necropsy showed similar or comparable lesions, the circumstances warranted more careful and detailed study.

The conditions found may best be summarized from the abridged notes of the necropsy examinations.

Case 1.—J. D., aged 22. Duration of illness, sixteen days. Lungs: Typical purulent tracheobronchitis and bronchopneumonia.

Sinuses: Sphenoidal sinus completely filled with a thick mucopurulent exudate under some pressure. Mucosae markedly swollen and deeply congested. Posterior ethmoids contained small amount of thin, yellowish fluid. Anterior ethmoids and frontals free.

---

* From the Central Medical Department Laboratory, A. E. F.

[1] For the larger part of the bacteriologic results in these cases, I am indebted to the careful, thorough work of Lieut. J. G. Hopkins, M. R. C. His painstaking labors, carried out under the most trying conditions, deserve more than passing mention.

[12] Hammond, Rolland and Shore: Purulent Bronchitis, Lancet, London, 1917, **2**, 41.

Bacteria: Influenza bacilli recovered from sphenoidal sinus, lung and liver. Occasional gram-positive cocci in pairs and short chains also present.

Case 2.—C. M., aged 23. Duration of illness, 23 days.

Lungs: Typical purulent tracheobronchitis and bronchopneumonia.

Sinuses: Left sphenoid filled by thick mucopurulent exudate under pressure. Both posterior ethmoids contained moderate amounts of pus. Mucosae swollen and reddened. Other sinuses free.

Bacteria: Cultures revealed *B. influenzae* in ethmoid, lung, bronchi and liver. Streptococcus also found in bronchus but not in ethmoid.

Case 3.—M. C., aged 27. Duration of illness, twenty-six days.

Lungs: Purulent tracheobronchitis and bronchopneumonia. Mucosae swollen.

Sinuses: Both sphenoids and posterior ethmoids full of thick, mucopurulent exudate. Mucosae swollen. Anterior ethmoids and frontals apparently clear.

Bacteria: *B. influenzae* recovered in pure culture from the sphenoidal pus and the lung, and in mixed culture from bronchi, spleen, liver and bronchial lymph nodes.

Case 4.—L. S., aged 23. Duration of illness, thirty-two days.

Lungs: Purulent tracheobronchitis and bronchopneumonia with fibrinopurulent pleuritis.

Sinuses: Sphenoidal, posterior ethmoidal and frontal sinuses filled with thick mucopurulent exudate. Mucosae swollen and reddened. Anterior ethmoids free but mucosae swollen.

Bacteria: Influenza bacilli from frontal, sphenoid, bronchus, lung and liver Pneumococci also in sphenoid and lung. From bronchus, practically pure culture.

Case 5.—M. H., aged 24. Duration of illness, twenty-nine days.

Lungs: Purulent tracheobronchitis, bronchopneumonia and fibrinopurulent pleuritis.

Sinuses: Mucosae of sphenoidal, ethmoidal and frontal sinuses swollen and reddened. In left sphenoid and both frontals were a few drops of mucopurulent exudate. Other surfaces were bathed by a mucoid fluid.

Bacteria: *B. influenzae* recovered from sphenoid, ethmoid, lung, bronchus and liver. Streptococci also found in sinuses.

Case 6.—A. C., aged 22. Duration of illness, twenty-nine days.

Lungs: Purulent tracheobronchitis, bronchopneumonia and fibrinopurulent pleuritis.

Sinuses: Sphenoids contained a few drops of thin mucopurulent exudate. Other sinuses free. Middle ears and mastoids on both sides showed thick pus.

Bacteria: Influenza bacilli obtained from sphenoid, middle ear, lungs and bronchi.

Case 7.—W. H., aged 22. Duration of illness, twenty-three days.

Lungs: Purulent tracheobronchitis with bronchopneumonia and fibrinous pleuritis.

Sinuses: Sphenoids, posterior ethmoids and right frontal contained abundant mucopurulent exudate, and mucosae were markedly swollen and congested. Middle ears on both sides showed similar condition.

Bacteria: *B. influenzae* found in sphenoid (associated with streptococci and pneumococci), bronchus, pleura and middle ears.

These cases have certain features in common which distinguish them on the clinical and the pathologic side. A purulent tracheobronchitis with patches of bronchopneumonia definitely identifies them as belonging to the "pulmonary type" of influenzal lesion. However, [illegible] instance either one or several or all the sinus[illegible] that ar[illegible]lved in what was usually a relatively s[illegible] t is no[illegible]atory process. It should be further [illegible] nciple [illegible] cases all occurred in young men, the [illegible] e vari[illegible]m 22 to 27 and averaging 23. As is usual with influenza, the duration was comparatively long, averaging over three weeks (twenty-four days), and ranging from sixteen to thirty-two days.

In view of the foregoing facts, especially the long duration, the question now arises as to whether, after all, these sinus infections are not merely sequelae or unimportant complications of the principal lesion, which, it may be contended with much reason, is located in the pulmonary system. In the course of our necropsy experiences, considerable evidence accumulated having some bearing on this point.

The following cases illustrate the presence of the syndrome described above, but with the added difference that death was in all probability due to other and seemingly independent conditions:

Case 8.—R. B., aged 18. Duration of illness, eighteen days. Death due to acute general miliary tuberculosis particularly involving lungs, spleen liver and brain, and arising from an older tuberculous lesion in a seminal vesicle.

Lungs: Acute purulent tracheobronchitis.

Sinuses: Sphenoids, especially the left, filled with thick, yellowish exudate, and lined by swollen reddened mucosae. Mucosae of ethmoids and frontals thickened and moist, but free from pus.

Bacteria: Influenza bacilli from sphenoids and bronchi.

Case 9.—J. M., aged 24. Duration of illness, three days. Death due to epidemic cerebrospinal meningitis.

Lungs: Purulent tracheobronchitis, with bronchopneumonia and seropurulent pleuritis.

Sinuses: Mucosa of sphenoid swollen, but all sinuses free from demonstrable pus.

Bacteria: *B. influenzae* obtained in culture from sphenoid, lung and bronchus.

Case 10.—G. T., aged 27. Duration of illness, thirty-nine days. Death due to scarlet fever. Complicating measles with terminal seropurulent peritonitis and pericarditis.

Lungs: Acute tracheobronchitis (not purulent), with acute serofibrinopurulent pleuritis.

Sinuses: Sphenoids, ethmoids and frontals contained considerable mucopurulent exudate, and mucosae were swollen. Middle ears both showed thick pus.

Bacteria: From the sinuses and middle ears, *B. influenzae* was obtained in cultures and smears. All the other lesions yielded hemolytic streptococci.

Case 11.—F. P., aged 19. Duration of illness, fifty-three days. Death due to double empyema (pneumococcic).

Lungs: Mucopurulent tracheobronchitis.

Sinuses: Sphenoids filled with a mucopurulent exudate. Mucosae swollen but pale. Ethmoids and frontals contained a small amount of mucoid fluid.

Bacteria: Influenza bacilli obtained in mixed culture from sphenoid. No culture taken of the bronchus.

Case 12.—F. B., aged 22. Duration of illness, eleven days. Death due to empyema and pericarditis complicated by pulmonary abscesses (all streptococcic).

Lungs: Purulent tracheobronchitis (pneumococcus, Type III).

Sinuses: Sphenoids showed swollen gelatinous mucosae, and contained a thin mucopurulent fluid. Remaining sinuses appeared normal.

Bacteria: Influenza bacilli obtained by culture from sphenoid.

Case 13.—H. P., aged 18. Duration of illness, thirty-five days. Death due to double empyema (pneumococcic).

Lungs: Acute purulent bronchitis (no culture made).

Sinuses: Sphenoid sinus filled (under pressure) with thick mucopurulent exudate. Mucosae swollen but pale. Remaining sinuses free.

Bacteria: From sphenoid, *B. influenzae* obtained by culture and smears.

As has been indicated, in these six cases, death was in all probability due to some other than an influenzal infection. What the interrelation was between the various infecting organisms furnishes an interesting speculation. That which concerns us at this time is the presence in all these cases of pathologic conditions in the sinuses in which the exudate harbored influenza bacilli that it is fair to presume were pathogenic. It must also be admitted that in some of the cases influenza organisms were possibly responsible for the conditions found in the bronchi and trachea; but certainly in these regions the pathologic processes were no further advanced than in the sinuses. It would not appear, at least, that the sinuses were necessarily secondarily or terminally invaded as compared with infection of the bronchial tree.

Further evidence is produced by two other cases in which sudden death was due to accidental causes:

Case 14.—A. S., aged 22. Duration of life after accident, 40 minutes. Death due to bullet wound through chest, involving heart and lungs.

Lungs: Bronchi apparently normal.

Sinuses: Mucosae of sphenoids swollen; cavities contained mucoserous exudate.

Bacteria: *B. influenzae* isolated from sphenoid in pure culture.

Case 15.—J. H., aged 30. Duration of life after accident, sixteen hours. Death due to fracture of skull and hemorrhage of brain.

Lungs: Bronchi apparently normal.

Sinuses: Left posterior ethmoid showed a few drops of thick mucopurulent exudate. Mucosae swollen and reddened. Other sinuses apparently free.

Bacteria: *B. influenzae* isolated in pure culture from this pus.

In both of these cases, with no macroscopic evidence of bronchial or tracheal involvement, definite inflammatory conditions associated with pure cultures of the influenza bacillus were found in the sinuses. Here, at least, the infection would appear to have been present in the sinuses before it became of any importance in the pulmonary tract. It might then have been a potential nidus for the future development of lung complications. Even granting that the sinus conditions were sequelae of a previous bronchitis from which the patients had recovered, the menace for recurrences and extensions would probably remain the same. After all, the question of whether the lungs or the sinuses were first affected is relatively immaterial compared to the importance of the facts themselves, namely, that the sinuses may be seriously involved in cases of influenzal bronchitis, and also that this infection of the sinuses may exist independently of any lung disease either as a consequence or a cause.

COMMENT

It would, of course, be unreasonable to assert that all cases of influenza are accompanied by sinus complications. While it is true that in only one of our cases of influenzal purulent tracheobronchitis coming to postmortem did we fail to find sinus disease also present, it is unfortunate that both in this case as well as in the others of the series the antrum of Highmore was not also investigated. However, the number of cases is altogether too small to justify any sweeping conclusions. They do serve most emphatically to emphasize the importance of the sinuses in the respiratory type of influenza.

This importance is interesting from two standpoints. First, from the standpoint of a local focus of infection, which not only constantly menaces the pulmonary system, only awaiting suitable conditions of exposure and lowered resistance for hostile invasion, but also furnishes continued sources of toxic absorption, not to mention the direct effect on the well being of the patient from the presence of these local conditions. Second, and more important, is the bearing that these local infections have on prophylaxis and treatment. When their attention had been called to the possible constant presence of sinus disease in patients suffering from influenzal bronchitis, the attending physicians adopted local measures of treatment for these conditions, even when their presence could not be diagnosed with any degree of certainty. Local applications to the nasal passages of cocain and epinephrin solutions often resulted in copious discharges of thick, mucopurulent exudate from the sinuses, with marked relief to the patient, such as amelioration of headache and pain in the eyes, as well as definite betterment of the conditions in the bronchi and trachea.

While the general proposition that young, otherwise healthy adults do not die from uncomplicated primary bronchitis or bronchopneumonia is by no means without exceptions, nevertheless, it is always extremely desirable in such cases to search most carefully for foci of infection other than the respiratory tract per se. The middle ears, serous membranes and even the blood stream may harbor the offending organisms, but in cases of influenza and possibly other respiratory diseases,[13] the sinuses of the skull should always be investigated and their freedom from involvement assured before other than general therapeutic measures of relief are abandoned.

Inevitably in these days, the question of carriers is linked up with that of actual cases, and perhaps too little consideration has been given to sinus disease as furnishing chronic foci for the spread of epidemics.

The entire subject deserves further investigation, and whether or not my conclusions are found to be justified, in the study of larger groups of cases and by other workers, is a matter of minor importance. If more careful attention is directed toward what at times is an important feature of epidemic influenza, namely, sinus involvement, this communication will have fully accomplished its purpose.

SUMMARY

1. Epidemics of respiratory influenza [illegible] tracheobronchitis) have been fairly severe [illegible] American and the British Expeditionary [illegible]

2. In the investigation of cases, both [illegible] at postmortem, little attention in the [illegible] given to the question of accompanying [illegible]

3. Of eight fatal cases of purulent [illegible] due to the influenza bacillus, all [illegible] involvement of one or more of the [illegible] of the skull by inflammatory processes, [illegible] cases, directly due to the invasion [illegible] the influenza bacillus.

4. In six patients that died from [illegible] ently independent infection, the [illegible] enzal inflammations.

5. Of two patients dying from [illegible] injuries, both harbored in their [illegible] pure cultures of *B. inflenzae*.

6. Appropriate treatment of [illegible] suffering from influenza [illegible] symptoms and apparently to [illegible]

7. Investigation of the [illegible] influenza is strongly recom[illegible] on therapeutic but also on [illegible]

---

[13] As, for example, whooping [illegible] influenza both in the character [illegible] many of the clinical features [illegible] some influenza patients is often [illegible] caused by the Bordet-Gengou [illegible]

THE TREATMENT OF AMEBIASIS

The recognition of the *Endameba histolytica* as the cause of that form of dysentery known as amebic dysentery, a disease endemic in many parts of the world and liable to occur in widespread, fatal epidemics, has been helpful in many ways. The identification of the parasite and its differentiation from other organisms at times inhabiting the alimentary tract of man has made the early accurate diagnosis of the infection more easy. It has also facilitated the problems of prophylaxis and therapy by furnishing dependable information respecting the specific form of life that must be combated. .

The most familiar specific therapy of amebic dysentery in recent years involves the use of ipecac and emetin. Thus, according to the Handbook of Therapy:[1]

> Whether the amebae are on the surface of the mucous membrane, deeply embedded in the ulcers, or localized elsewhere in the body, they may be reached by properly administering ipecac and emetin. The amebae on the surface of the mucous membrane are not likely to be affected by emetin administered hypodermically. On the other hand, emetin given hypodermically becomes more quickly active on the deep seated organisms and the localized lesions. . . . Happy though the results of this combination may be in treating amebiasis, the fact should not be overlooked that emetin is an amebacide and has little to do with the healing of ulcerations. Every case of amebiasis should, after this treatment, be considered one of ulcerative colitis and so treated from a dietetic point of view. At the same time every effort should be made to enhance resistance by change of climate, tonics, etc., to obviate the distressing sequelae characteristic of the disease.

Dale and Dobell[2] of the Medical Research Committee in London have lately made a somewhat rigorous test of the action of substances that already have gained or are likely to gain a therapeutic reputation in amebic dysentery. These studies have brought evidence of an unmistakable discrepancy between the action of emetin, in particular, and likewise other substances in vitro and their curative effects in dysentery. The earlier assumption on which the use of ipecac alkaloids was based attributed their favorable effect to a direct amebacidal action. Dale and Dobell found that emetin and the other alkaloids of ipecacuanha, as well as artificial derivatives, exhibited no characteristically high toxicity for the amebas, when compared with that of some other alkaloids. Methylpsychotrin, a natural alkaloid from ipecacuanha, which is more toxic for *Endameba histolytica* when tested in vitro, and much less toxic for mammals than emetin, appears to be entirely devoid of therapeutic action even when it is given in large doses.

There is clearly some other factor, Dale and Dobell conclude, in the cure of dysentery by emetin, than the alkaloid and the amebas; and that factor must be supplied by the host. The participation of the host in the process is believed to be further evidenced by their observation that emetin has no appreciable effect on the course of amebic dysentery in the cat, while it cures the disease in man, even when the same strain of amebas is present in the two hosts. It should be remembered that the *Endameba histolytica* is an obligate parasite which, unlike some other amebas that survive in the contents of the bowel, can live and multiply only by invading the tissues of its host. Perhaps, therefore, the effective drugs act by promoting some natural defensive reaction to invasion. In any event the theory of the mode of action of emetin in amebic dysentery needs reconsideration; and on its correct formulation rests in no small measure the possibility of selecting other suitable amebacides.

THE HOUSEFLY IN SPRING

Why flies are both a nuisance and a menace to health scarcely needs any longer to be explained. The smallest schoolboy has been taught to look on these little insects as enemies that must be conquered. Something more than flytraps and flypaper and screens are requisite for a successful campaign. We may continue to "swat the fly" with unabated vigor for years to come; but until the life habits and reproductive phenomena of this species are clearly understood so that scientifically founded plans for the conquest of the objectionable creatures can be put into operation, progress will scarcely be demonstrable. Sanitary and medical projects have need of the entomologist in this as in various other modern problems that bear on animal welfare or human health and comfort.

Of flies it is well known that they are attracted by most forms of food and putrid substances, and that they breed where food and mediums for the deposition of eggs are available. This is particularly the case in manure. It is also realized that the temperature plays an important part in the activities of the insects. They disappear from view in cold weather. Do they persist during the winter season? Can they winter over in protected or slightly heated locations, or is the appearance of the housefly in the spring connected with other factors? A government entomologist[1] has supplied the answer to some of these queries, not by haphazard methods but by careful observations extended over several years in the vicinity of Washington. There is no evidence whatever to show that houseflies do or can persist as adults from November to April, either outdoors, in protected stables, or in attics or heated buildings. Temperatures of from 12 to 15 F. are quickly fatal, and there is every reason to believe that any temperature below freezing is fatal if continued long enough. In heated buildings their life is not prolonged beyond that of summer at like temperature, nor is there any suspension or retardation of sexual development or activity.

---

[1] Handbook of Therapy, Ed. 4, Chicago, American Medical Association, 1915, p. 265.

[2] Dale, H. H., and Dobell, C.: Experiments on the Therapeutics of Amoebic Dysentery, Jour. Pharmacol. and Exper. Therap., 1917, **10**, 399.

If adult houseflies appear, as they sometimes do most unexpectedly in isolated instances in midwinter, it is because they represent the result of continued breeding in warm places where food and mediums for deposition exist. Many of the late forms will find their way on mild days to heated buildings. Those that do not are quickly killed. The more successful flies, Hutchison[1] reminds us, are attracted, as in summer, to odors of food, and will congregate in kitchens, dining rooms, restaurants, bakeries, animal houses, and the like. If no food is at hand they will quickly perish. When food is available, they may continue alive through December and January and even into February, if not destroyed by fungus attacks. But there are neither experiments nor observations to show that they can continue throughout the winter until temperatures are again favorable for outdoor activity and egg laying. If flies find access in the autumn to heated buildings, where both food and mediums for deposition are available, such as animal houses or restaurants in which sufficient attention is not given to the disposal of garbage or kitchen wastes, they will continue breeding throughout the winter. In such cases the flies present in March and April are the offspring, not the survivors, of those that found their way to such places the preceding autumn. Thus, Hutchison adds, it is probable that this method of overwintering is much more widespread than is now realized, especially in cities, where there must be several foci from which flies escaping on warm days in March and April survive to produce the hordes that begin to appear late in May.

In the case of the larva and pupa stages, it must be admitted that the fly can overwinter where conditions are not too rigorous. The government entomologists are uncertain as to whether overwintering in these stages or by continued breeding is the more common or more successful. The chances are that few, at most, of the larvae present in manure in the autumn can survive until the following spring. These observations show clearly that the winter months in the colder climates afford a chance to make a good beginning in the control of the fly nuisance in the following summer. It is our neglect of filth in which flies can breed that undoes the good which the fly-killing cold weather has bestowed without cost.

THE POMELO, OR GRAPEFRUIT

Grapefruit is a popular name for the edible fruit of *Citrus decumana*, now widely used in the dietary of American households. Although the designation pomelo has been adopted in scientific circles in this country, and the fruit is termed "pomelow" by the English of Ceylon and India, the now familiar expression grapefruit, selected in recognition of the fact that the fruit commonly occurs on the trees in large clusters somewhat resembling those of grapes, is likely to be retained. The name "shaddock," which was likewise employed by some a few decades ago, is all but abandoned now.

Although even younger persons can recall when grapefruit was comparatively rare as a component of our regimen, it is not easy to realize that the first shipments from Florida were made subsequent to 1880. As late as 1885 the fruit was described as "more showy than useful," while it was incidentally noted that the juice is rather refreshing.[1] Despite the fact that literally thousands of carloads of grapefruit are annually shipped to market now in this country, only the scantiest information about a fruit found on so many American tables is actually available in easily accessible literature. It is helpful, therefore, to find that the United States Department of Agriculture has begun to fill the gap in our knowledge with some dependable information regarding the composition of the grapefruit.[2]

The edible portion — the pulp or juice — deserves first attention from the dietetic standpoint. It contains sucrose and reducing sugars in about equal proportions, the total reaching 30 gm., or approximately 1 ounce, in a large specimen of some varieties in which this part may weigh three quarters of a pound or more. Thus a diabetic indulging in half a grapefruit may readily ingest from a quarter to half an ounce of sugar in a product in which this may be unsuspected, owing to the sour taste. The latter is due, as in the case of other citrus fruits, to citric acid, the content varying from about 2 to 6 gm. per fruit, depending on the size, variety and stage of ripeness or storage. Whereas the sugars increase during storage, the acidity decreases.

The peel or rind of the grapefruit offers not a little of interest to the chemist. The essential oils are represented by limonene, citral, pinene and alcohols. Beside the pectin there is, further, a glucosid naringin which is synonymous with the "bitter principle" of the fruit. Whether this compound, in particular, and other components have any pharmacologic potencies remains to be ascertained. Nevertheless, therapeutic efficacy has been ascribed to the pomelo by more than one writer. Evidently the bitterness has suggested the potency of quinin or a similar alkaloid; hence the assurance that "a cool, juicy pomelo before breakfast is one of the pleasantest and surest antidotes imaginable for malaria." It is stated that subtropical or tropical countries are prone to offer grapefruit or similar citrus fruits as a safeguard against malaria, and publications from these sources contain similar advice.

[2] Zoller, [illegible] Some Constituents of the American G[illegible] (Citrus D[illegible] [illegible]ur. Indust. and Engin. Chem., 1918, **10**.

We may well enjoy the luscious grapefruit, content with its small modicum of nutriment and large share of pleasures of the palate. The juice fruits are not selected primarily for their supply of calories. They have other compensating virtues which put them in the class of acceptable dietary accessories. One need merely recall the antiscorbutic properties of the orange — and possibly of citrus fruits in general. The government expert has sounded the proper note of warning in these words:[2]

> The dailies and periodicals of promoters in citrus fruit sections abound in attractive quackery on the beneficent medicinal properties of all citrus fruits, and especially grapefruit. This remedial property is being assigned to everything present in the fruits—the "alkaloids" said to be present, the citric acid, the potassium phosphate in the pulp, and the oils in the peel. If it is upon the oil present that we must depend for this elixir, then a tablespoonful of pure gum-turpentine will furnish the same amount of remedial as an entire crate of citrus fruit, providing we eat the peel and all. If it is due to the phosphoric acid as phosphate, as Dygert would have us believe, then a glass of cow's milk would be equivalent to a dozen grapefruit in this life-giving entity. If it is due to the alkaloids present in the citrus fruits, then they have no therapeutic value, for no alkaloid has been detected in any of the citrus fruits regularly marketed in this country, and it is not likely that an alkaloid exists in any of the citrus family.

ABSORPTION THROUGH THE VAGINA

It has long been established that the sound skin is practically impermeable for watery solutions of salts and other substances. For this reason, perhaps, it has become customary to think of other surfaces closely connected with the integument as being similarly impervious to soluble products that come into contact with them. Yet everyday experience in ophthalmologic practice bears witness to the permeability of the epithelial membranes of the eyes to the drugs used in dilating the pupil for purposes of examination of these organs. Furthermore, the history of toxicology shows clearly that another structure — the vagina — which resembles the skin in many respects, except for the absence of the horny surface as its outer layer of stratified epithelium, can also be the seat of active absorption. Nevertheless, as Macht[1] has pointed out in an elaborate study of the vagina as a seat of absorption, the vagina is generally regarded as an organ incapable of absorbing pharmacologic agents. Witness to this widespread belief, he says, is the universal and indiscriminate employment by women of all kinds of medicaments — some known to be innocuous and others recognized otherwise as violent poisons — in the form of douches, tampons, suppositories, "uterine wafers," and the like.

The numbers of cases of serious intoxication due to the introduction of mercuric chlorid in solution into the vagina seems to be increasing. Clinical literature gives instances of various other harmful substances that have found their way into the organism through the vaginal membrane in sufficient amounts to give evidence of their absorption. Arsenic, zinc sulphate, iodoform, belladonna and phenol (carbolic acid) are included in the list. The excuse for these facts may perhaps be found in the still prevalent opinion that drugs applied to the vagina exert only a local effect, and cannot penetrate further into the system. Only on such a hypothesis could the almost indiscriminate employment of vaginal douches containing potent substances have been tolerated or acquiesced in, and local treatments with solutions of drugs complacently adopted by so many physicians in the past. When an untoward result has been observed, it has usually been attributed to an escape of fluid into the uterine cavity; but, according to Macht, a review of the literature reveals the fact that in many of the authentic cases described this explanation must now be abandoned in favor of absorption through the vagina.

The situation that prevails lends much significance to Macht's latest experiments in this field. From these it appears that all kinds of pharmacologic agents — alkaloids, inorganic salts, esters and antiseptics — can be absorbed with comparative ease through the vaginal walls. Macht points out that, from a therapeutic point of view, drugs such as opium or belladonna may be rationally administered for their constitutional effects through the vaginal route when suitable circumstances arise. But probably a greater emphasis needs to be placed at present on the danger that centers in the careless employment of poisonous substances that may find entrance to the organism in this hitherto unsuspected way. It is not unlikely that, in view of the widespread use of douches, etc., occasional chronic intoxications of unexplained origin may find their explanation in the absorption of the harmful substance through contact with the vagina.

War and the Sciences.—In spite of the fallacy of the German philosophers, they have, nevertheless, established in the German people action patterns of such surpassing strength that in the organized intelligence of the German people is our greatest menace. In fact, the present war is a contest of ideas rather than of men. In its broad sense it is the practical application of physics, chemistry and biology in a mass struggle for the existence of nations.—G. W. Crile, M.D., *Pennsylvania Medical Journal.*

Current Comment

ONE NON-ESSENTIAL INDUSTRY

The question as to what constitutes a non-essential industry in war time cannot be answered offhand. The complexities of modern business are such as to make it extremely difficult to determine just what industries should be suspended under the stress of war conditions without inflicting a greater economic injury than is justified by the possible benefits that might accrue. There is one business, however, that those who have given the problem any study would have to admit should be largely dispensed with during the war — and might properly be largely dispensed with at all times — and that is the manufacture of nostrums. Every physician and every druggist knows that there is not a "patent medicine" on the market today whose place is not better filled by official products that are found on the shelves of every druggist in the country. Every physician and every druggist knows that the "patent medicine" maker aims, not to furnish drug products that can be obtained in no other form, but to duplicate in infinite variety, with secret mixtures, the non-secret preparations already on the druggists' shelves and, what is far worse, to stimulate unnecessary self-drugging on the part of the public. It is true that, if the "patent medicine" industry were destroyed, druggists would for awhile suffer financial loss, not because they derive a large profit from "patent medicines," but because the public, being deprived of the lying scare-heads of "patent medicine" advertisements, would buy fewer drugs of every kind. Certainly, however, this loss to some thousands of druggists would be an immeasurable gain to some millions of people. The exploiters of a widely heralded nostrum have bragged in their advertisements of the number of carloads of their mischievous alcoholic mixture that they have shipped to certain points. Does even the intelligent layman believe that under present conditions there is any excuse for taking up valuable shipping space with such worthless, if not dangerous, trash? And this is but one of scores. If there is one industry in the United States whose suspension at the present time is justified on the grounds of public health, greater efficiency and avoidance of waste, it is the nostrum industry.

THE MEDICAL DEPARTMENT AND THE GENERAL STAFF

The General Staff of the Army is the most important body connected with the prosecution of the war. One of the vital phases of the war is the physical condition — the health — of the soldier. It is an anachronism, therefore, that the Surgeon-General of the Army is not included in the General Staff. A recent issue of the Army and Navy Register reproduces a photograph of the Navy War Council in session; prominent among its members is the Surgeon-General of the Navy, Admiral Braisted. Somehow the Navy seems to set the pace for the Army in constructive legislation relative to medical administration; somehow the Medical Department of the Army seems to be regarded as of minor importance. Why, we do not know. Elsewhere in this issue we print the text of a bill recently introduced into the House of Representatives by Mr. Hicks to remedy the present condition. It is to be regretted that this bill includes anything more than this first section:

> "That hereafter the Surgeon-General of the Army shall be a member of the General Staff Corps, and that the number of officers of the General Staff now authorized by law be increased accordingly."

Certainly there can be no reasonable opposition to this particular part of the Hicks' bill.

THE NEW YORK HEALTH DEPARTMENT

In referring to the reactionary forces in New York that seemed to be making a political football of that city's Health Department, The Journal called attention to the fact that the efficient work of two of the bureaus of the New York Health Department had interfered with the malignant activities of certain interests. These were the Bureau of Public Health Education, headed by Dr. Charles F. Bolduan, and the Bureau of Food and Drugs, under the direction of Lucius P. Brown. Dr. Bolduan has persistently fought quackery and the nostrum menace and given the New York public many interesting facts regarding these insidious evils. The bureau headed by Mr. Brown had made it interesting for the sophisticators of foods and drugs. Since The Journal commented on the New York situation, Dr. Bolduan has been let out while Mr. Brown has been suspended! Significant, isn't it?

METABOLISM IN GOUT

The fact that the treatment of gout is very unsatisfactory and that the disease is notably intractable furnishes an added stimulus to the study of its phenomena and their presumable causes. Lusk[1] has remarked, in discussing this baffling disease, that just as the whole trouble in diabetes turns on the ability of the organism to destroy sugar, so the symptoms manifested in gout are dependent on the deposit of acid urate of sodium in certain localities. But analogies may be misleading in science. In diabetes there is an undeniable upset in the metabolism of the carbohydrates, and at certain stages doubtless also a perversion in the transformations or oxidations of other foodstuffs, notably the fats. Are we to infer that gout is a disease of metabolism in a similar sense? This question has often been asked with respect to the behavior of the purin compounds, the precursors of uric acid in metabolism. One by one the props to the older structures of the theories of the gouty diathesis have been taken away by the disclosures of experimental investigation. Gout is not due to an increased formation of uric acid, as was once believed; nor is there any evidence that the accumulation of this substance is due to a diminished destruction. Gradually attention has been focused on a change in the renal functions in gout.[2] But the question of some fundamental upset in metabolism always reasserts itself, despite the accumulated evidence that, aside from possibilities of the now denied altered metabolism of the purins, the general chemical exchanges in the body are the same in gout as in health.[3] The latest investigation, a study of the heat production of gouty persons as calculated from their oxygen consumption, shows anew that the basal metabolism falls within normal limits. Purin-yielding foods produce no change in intermediary metabolism sufficient to be detected by the method of indirect calorimetry. These observations, made by Wentworth and McClure[4] in the medical clinic of the Peter Bent Brigham Hospital, Boston, cannot exclude disturbances in "some minor phase of intermediary metabolism produced by nuclein-rich foods"; but if such exist they are surely too slight to affect the basal metabolism of persons subject to gout.

THE ACTUALITY OF COLD STORAGE IN THE FOOD SITUATION

The world war has taught us to revise our judgment on many subjects, notably in respect to foods and their distribution. Never before has this nation realized so clearly that the important staple perishable foods produced as articles of commerce must be preserved in the season of production and plenty, and carried over through the winter period by some suitable plan of conservation. Desiccation and canning have received a new impetus; old practices have been restored and new ones devised in the attempt to save and prevent the spoiling of what is perishable. The stigma has been removed from many products and procedures which in the immediate past have been obliged to contend with the prejudice of conservatism or the reaction against novelty. The cold storage process has thus succeeded in winning a better understanding for itself, so that refrigeration plants have come to occupy a recognized place in the food conservation plans. Part of the confusion about them lies in the misunderstanding of their proper uses. A cold storage warehouse "shall mean any place artificially or mechanically cooled to or below a temperature of 45 degrees above zero Fahrenheit, in which food products are placed and held for thirty days or more." The waste of fruits and vegetables cannot be prevented satisfactorily by application of cold storage, except in the case of a very few products, such as apples, pears and perhaps potatoes and onions. Nevertheless, the industry is not idle. Some conception of its capabilities is furnished by recently compiled data.[5] The combined total cold storage and packing house capacity now available or immediately proposed is nearly 500,000,000 cubic feet. To cite a few conspicuous items, this includes more than 100 million pounds of butter, nearly 800 million pounds of cheese, 7 million cases of eggs, 5 million barrels of apples, and more than 100 million pounds of poultry, without mention of the stores of meats of many varieties. In the case of meat, butter, lard, eggs, cheese and apples alone, the value of the products stored presumably far exceeds $200,000,000.

POSSIBLE HEREDITY IN BRAIN CONVOLUTIONAL PATTERNS

The study of heredity has thrown a flood of light on the inheritance of peculiarities that characterize individuals and produce certain types of resemblances between relatives. Recurrences of form and stature, color and skin patterns, psychologic similarities and even chemical oddities of metabolism like cystinuria and alkaptonuria have been shown to fall within the schemes of explanation developed by students of genetics, and particularly as a result of experimental investigations of mendelian problems. Blue eyes and red hair and polydactylism have become amenable to interpretation in accord with established "laws of heredity." The internal organs have not yet been subjected to equally intensive research in the light of these newer generalizations. Recently, however, Sano[1] has directed attention to the possibility of hereditary resemblance in the study of the convolutional patterns of human brains, at the London County Asylums. The seeming intricacies of the convolutions and fissures of the cerebrum almost bar an adequate analysis of a problem thus complex. Nevertheless, a control of comparisons with nonrelative brains has enabled Sano to assert that the brains of relatives — brothers, parents and children — are more like one another than those of nonrelatives. This appears to be particularly true when, as in negro or other races, the types are less mixed than is the case among most British subjects. What such studies of pattern in organs may lead to no one can conjecture at present.

THE BLOT ON THE ESCUTCHEON

A reminiscent article, prompted by the death of a "patent medicine" millionaire, recently appeared in a metropolitan paper. Generalizing on the ultimate distribution of the wealth made in the nostrum business the writer says:

> The dispersal of many large fortunes accumulated in the making of pills and "cures" rarely attracts attention. The beneficiaries generally strive to hide the sources of their enrichment. A dozen cases might be mentioned of Philadelphia, Providence, Newport, and New York families whose money came from such sources, but whose members of this generation studiously avoid mention of the fact.

Well, one can hardly blame them!

Disease Prevention.—Surely our philanthropists should find as much pay in preventing misery as they do in relieving it. Preventive medicine is the watchword of the hour, and enlistment in the cause can come only through education.—M. J. Rosenau.

Association News

TWO IMPORTANT SPECIAL MEETINGS AT THE CHICAGO SESSION OF THE AMERICAN MEDICAL ASSOCIATION

Examination of Registrants—Rehabilitation of the Disabled Soldiers

The medical profession is particularly concerned with two points in the life of the soldier—one, when he enters the Army; the other, when, physically disabled, he is no longer a fighting unit. A careful selection of recruits protects the government—which means the people—against admission to the Army of men not physically fit—men who probably would become a source of expense as long as they live. When the soldier is disabled it becomes the duty of the government to restore him as nearly as possible to perfect physical condition, and to do all that is possible to fit him to fill a position in life that will not make him dependent on others for support.

THE EXAMINATION OF RECRUITS

Two important special meetings in connection with the annual session of the American Medical Association next month will be devoted to these phases of the soldier's life. The first subject will be considered on Thursday afternoon and Friday, in meetings held at the Studebaker Theater. The importance of these meetings to physicians will be appreciated when it is realized that there are between 23,000 and 25,000 physicians connected with the examination of registrants.[1] The opening meeting will be addressed by a representative from the Provost Marshal-General's Office, by some one representing the local boards, the advisory boards, by a layman to present the public's view, and by an Army medical officer representing those concerned with the final examination of recruits. The aides to the governors of the various states will be present by order of the Provost Marshal-General. At 8:30 to 10 o'clock Friday morning a meeting of the state aids will be held. The rest of the day will be devoted to a conference of all physicians engaged in the examination of registrants on various problems connected with the work, and to an explanation of the new regulations which will be ready for distribution at that time.

RECONSTRUCTION AND REHABILITATION

The meeting on reconstruction and rehabilitation of the disabled soldiers, arranged for all day Thursday at the Auditorium Theater, as was announced week before last, will consider the various phases of this timely subject—the national program; the experience of foreign countries; the transportation from overseas; reconstruction of the special senses; reclamation of the industrial workers; vocational training—in fact, every aspect of the subject will be considered by special workers and by students of the subject.

Both of these special sessions should be—and undoubtedly will be—largely attended.

THE CHICAGO SESSION

Meetings of the House of Delegates

The House of Delegates will hold its meetings during the coming annual session in the library at the headquarters of the Association, 535 North Dearborn Street. The first meeting will convene at 10 o'clock Monday morning, June 10, continuing in the afternoon. On Monday and on Tuesday, arrangements are made for the House to recess between 12:30 and 2 o'clock, when luncheon will be provided at the Hotel Virginia for the members of the House. On Monday evening the members of the House will be the guests of the Chicago Medical Society at the Hotel La Salle where a buffet supper will be served to be followed by a smoker.

Entertainment for Women Guests

Mrs. Albert J. Ochsner, chairman of the Committee on Women's Entertainment, announces the following entertainments for the wives of physicians and other women guests in attendance at the annual session:

Tuesday afternoon, June 11, informal "at home" at the Chicago Woman's Club under the auspices of the president of the Woman's Club and the Committee on Women's Entertainment.

Wednesday afternoon, June 12, a "tea" at the South Shore Club from 2 to 5 p. m. At this entertainment there will be an excellent musical program.

Thursday afternoon, June 13, reception at the Art Institute.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 17, 1918, the personnel of the Medical Department of the Army included:

Medical Corps: 869, including 1 major-general, 65 colonels, 110 lieutenant-colonels, 298 majors, and 395 lieutenants.

Medical Reserve Corps: 18,951, including 1,320 majors, 4,794 captains and 12,837 lieutenants. On active duty: 16,926, including 1,229 majors, 4,462 captains and 11,235 lieutenants.

Medical Corps, National Guard: 1,202, including 20 lieutenant-colonels, 244 majors, 151 captains and 787 lieutenants.

Medical Corps, National Army: 125, including 3 brigadier-generals, 14 colonels, 100 lieutenant-colonels and 8 majors.

Dental Corps, 209; Dental Reserve Corps, 5,275, of whom 1,518 are on active duty; Dental Corps, N. G., 257; Veterinary Corps, 17; Veterinary Reserve Corps, 1,443, of whom 733 are on active duty; Veterinary Corps, N. G., 40; Veterinary Corps, N. A., 496; Sanitary Corps, 1,095, and Ambulance Service, 162, constitute the remainder of the commissioned personnel.

The Discharges in all branches of the service to date are:

	Number				
Causes	M.R.C.	M.C.N.G.	D.R.C.	D.C.N.G.	San.C.
Physical disability	659	52	13	8	7

General Hospital Bulletin

The initial copy of "The Bulletin of the U. S. Army General Hospital No. 2" of Fort McHenry, Md., has just been received. This bulletin is to be issued monthly and is published by, and primarily for the benefit of, the medical and administrative staffs of the hospital, for a three-fold purpose: 1. To present such items of interest as administration at the hospital, important army orders of a public nature, legislation and personal notes; 2. to report cases of especial interest; 3. to be a permanent historical record of one of the largest government general hospitals which is built on the spot which is the birthplace of the national anthem. It is also aimed through the medium of this bulletin to bring about a closer cooperation of the staff of officers.

Interchange of War Prisoners

The *Riforma Medica* relates that the surgeon-general of the Swiss army has finally succeeded in arranging for the interchange between Germany and France of prisoners over 48 years old who have been in captivity for at least eighteen months. The officers in this group are to be interned in Switzerland, and the others repatriated. The commission that selects these prisoners for exchange is composed of three Swiss physicians and three physicians of the nation holding the men prisoners. The incurable and the tuberculous are also listed for repatriation and injury from an accident while at work is accepted as the equivalent for a war injury. Holland, after a year of overcoming difficulties, is said to have about completed similar arrangements for British and Teuton prisoners. There are about 8,000 C and the same number of British prisoners who will benefit by this interchange. In Italy the repatriating trains of the disabled arrive monthly. The last brought back to Italy 350 disabled soldiers and eighty officers. Besides this, there is also a weekly repatriating train of sick prisoners who are taken charge of by the Italian Red Cross as they cross the border.

---

[1] There are 156 district boards, 4,643 local boards, and 1,320 medical advisory boards. It is estimated that there are 15,000 physicians connected with the local and district boards. This estimate includes not only the medical members, but also the medical consultants and medical assistants utilized by the medical men on the boards. The number of members of advisory boards is approximately 9,500.

Medical Students Exempted from the New Draft

Senate Joint Resolution No. 124 provides that medical students in bona fide attendance at recognized medical schools shall be exempt from draft under the Selective Service Law of May 18, 1917. The resolution has passed both houses of Congress and presumably will receive the approval of the President. Medical students who have attained the age of 21 years since June 5, 1917, and on or before June 5, 1918, the day set for registration by proclamation of the President; will, like all other men of the same age period, be required to register; the time and manner of claiming exemption will be defined hereafter.

No medical student entering college after the approval of the resolution is entitled to exemption. Any student entitled to exemption loses that right as soon as he ceases to be a medical student in a recognized medical school, whether his status as a student is terminated by the interruption of his medical course or by graduation.

Students of dentistry are granted no exemption by the resolution.

A Bill to Increase the Efficiency of the Army Medical Service

A clear-cut statement of the principal needs of the Army Medical Service, and a succinct and well-defined plan to meet them, are embodied in a bill introduced into the House of Representatives on May 16, by Mr. Hicks. The bill, entitled A Bill providing that the Surgeon-General shall be a member of the General Staff Corps, and for other purposes, H. R. 12,141, was referred to the Committe on Military Affairs. It is as follows:

> *Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,* That hereafter the Surgeon-General of the Army shall be a member of the General Staff Corps, and that the number of officers of the General Staff now authorized by law be increased accordingly.
>
> Sec. 2. That the Secretary of War shall take such measures as will fix the responsibility for sanitary defects upon the proper commanding officers.
>
> Sec. 3. That no permanent camp, cantonment, post, or station which is to be occupied by troops be established unless its selection has been duly considered and formally reported upon by the Medical Department.
>
> Sec. 4. That when a state of war exists the transportation necessary to transport medical and hospital supplies of all kinds, and the sick and wounded of the Army, whether by land or water, shall be under the exclusive control of the Medical Corps.
>
> Sec. 5. That hereafter the commissioned officers of the Medical Corps and of the Medical Reserve Corps of the United States Army on active duty shall be distributed in the several grades in the same ratios heretofore established by law in the Medical Corps of the United States Navy.
>
> The Surgeon-General shall have authority to designate as "consultants" officers of either corps and relieve them as the interests of the service may require.

"WHY IS MY SOLDIER SICK"

Antivivisectionists, Misrepresentation Exposed

(Dr. Keen to the Secretary of War)

Hon. Newton D. Baker,
Secretary of War,
War Department, Washington, D. C.

My Dear Mr. Secretary:

In a four page pamphlet entitled "Why Is My Soldier Sick?" issued by the National Antivivisection Federation, incorporated, with headquarters at 456 Fourth Avenue, New York City, are published two resolutions passed by the New York Antivivisection Society at its annual meeting, Jan. 31, 1918, and forwarded to you officially. The second resolution reads as follows:

> *Be it further Resolved,* That a copy of the foregoing resolution be forwarded to the Secretary of War as our official protest against the medical department's claim that serum inoculation is a necessary war measure and for that reason made *compulsory,* and as our protest against compulsory inoculation when *the individual* soldier conscientiously objects thereto; and *we point to the provision of exemption now made by Great Britain, that power having been forced to rescind the rule of compulsion after the alarming effects of inoculation were disclosed.*[1]

It has long been a matter of common knowledge and deeply regretted by the medical profession that Great Britain has never made antityphoid vaccination compulsory, as it fortunately is in our own Army.

In an article entitled "The Red Cross and the Antivivisectionists," a copy of which I am enclosing, I have shown by irrefutable facts how extraordinary the protection of the antityphoid vaccination has been in our Army and in the British army.

Although I knew that the statement in this resolution was an absolute falsehood, I preferred to have an authority which was beyond all question. Accordingly, on Saturday, April 27, I sent the following cable to Surgeon-General Goodwin, who occupies the same post in Great Britain that General Gorgas does in this country:

> Surgeon General Goodwin, War Office, London:
> Has antityphoid vaccination ever been compulsory in British Army?
> Keen.

To this on Monday, April 29, I received the following reply:

> London, Prof. Keen, Philadelphia:
> Antityphoid inoculation has never been compulsory in British Army.
> Goodwin.

You will observe, therefore, that this is a flat contradiction of the false assertion of the New York Antivivisection Society.

Nearly all of the British army has been voluntarily vaccinated against typhoid fever. Col. F. F. Russell in Surgeon-General Gorgas' office authorizes me to say that he understands that 99 per cent. of the British soldiers are vaccinated against typhoid fever. The reason for this is that they have seen how extraordinarily complete is the protection offered by the antityphoid inoculation. At this time the fate of the war depends largely on the health of our Army. It is in my opinion equivalent to disloyalty to deprive our soldiers of this protection and sacrifice their lives instead of the lives of a few rabbits, guinea-pigs, cats and dogs.

Yours very respectfully,
W. W. Keen.

[Note.—
And the parson made it his text that week and he said likewise,
That a lie which is half a truth is ever the blackest of lies,
That a lie which is all a lie may be met and fought with, outright,
But a lie which is part a truth is a harder matter to fight.
Tennyson.]

Treatment of War Prisoners in Germany and Austria —A Russian Account

Dr. D. P. Nikolsky of Petrograd has been compiling data from the testimony of repatriated and escaped war prisoners in Germany and Austria, especially of physicians and nurses, and of commissions sent to inspect prisoners' camps. He is publishing his report in the *Russkiy Vrach,* and the first two instalments have been received. The dates of these issues are Aug. 12 and Nov. 25, 1917, pp. 468 and 562. He comments on the Germans' having revived the ancient barbarian custom of killing war prisoners or making slaves of them, and he quotes the minister of foreign affairs, Dohlbrank's, endorsement of the deputy Wohlschmidt's suggestion to "starve the war prisoners in view of the scarcity of provisions for our own German nation." The policy, Nikolsky says, "is to feed them only enough to keep them from dying of starvation and give them warmth only enough to keep them from freezing." And even this was not always done. He states that everything was taken from the captives at once, heavy coats, jackets, and shoes as well as money, watches and identification amulets, crosses, etc. In exchange they were given old worn-out things, slippers or wooden shoes. All had to submit to this plundering, officers and physicians as well as privates. Dr. Selezneff complained to the commanding officer when his watch and chain were taken, but the officer remarked to a younger officer, "He is lying," and told the physician that if he repeated this lie he would be given twenty-five stripes.

---

[1] Italics my own.

The prisoners were driven from the battlefield to the railroad without food, sometimes for seven or eight days. The inhabitants (Hungarians) heaped abuse on them, calling them "swine" and "dogs," throwing sticks and stones at them, striking them and kicking them, spitting in their faces and even tearing off the bandages from the wounded. Not only men but women took part in this abuse, and children, large and small. There were instances when the wounded or exhausted fell and the guards bayoneted them and threw them into the ditch. A party of prisoners taken at Brezin did not get any food for six days. Two of the captives slipped into a field to pick up partly rotten potatoes, but the convoy shot one and bayoneted the other. In some places they were offered bread and milk by Slavic or Polish residents, but the guards prevented their taking them or took the food away from the "Russian pigs." In some cases they had no food for nine days except discarded potatoes in the fields. Prisoners taken at the Mazurian lakes were given nothing to eat for seven days. When the prisoners reached the railroad station they were given alleged coffee, without sugar or milk, or a vegetable soup. Then they were herded in cattle cars, eighty or ninety men to a car in Germany, sixty or seventy to the smaller Austrian cars. They were not allowed to get out of the cars to attend to the calls of nature, and they had to make shift by using their caps, cloth torn from their shirts, etc., throwing them out of the car through the ventilating holes under the roof. "Some succeeded in dying in the car," one of the escaped prisoners tells, but the corpses were not taken out. Coffee and bread in small amounts were given after two or three days of this. When they stopped at a station, women in nurses' uniforms had provisions for the guards but none for the captives. Dr. Valuisky relates that when his train reached Naisse not even the wounded or the physicians were given anything to eat, but the women spread a feast for the convoy directly in front of the car with the wounded. Appeals for drinking water were unavailing. When some one brought a jug of water to the car, the guard pushed him away and poured out the water, saying "Nothing for the Russian swine." Such instances were common. Nikolsky quotes from a Russian paper Colonel Mislaivsky's story of the nurse spitting into a glass of water and flinging it into the face of a prisoner who had asked for water for a wounded comrade.

In the camp at Dunaserdagen the prisoners tore down the only building in the camp, the privy, and used the boards to strengthen the walls of their dugouts. But for this, the commanding officer had twenty of the prisoners shot and others bayoneted. As sickness became rife, shelters were built for the prisoners, long open sheds without walls. Finally walls were added, but, as one prisoner relates, "a sparrow could have flown through the cracks." Few had any stoves, and when there was a stove there was not enough fuel to heat it. Frozen feet and hands were common. Some of the Austrian barracks were of the actual prison type, with barred windows, no light or ventilation, and primitive arrangements in the building for latrines. In some of the camps, on the other hand, the latrines were at a long distance from the barrack and the prisoners were allowed to go to them only in platoons of ten under a guard convoy. At night, a platoon could be made up of five. Dr. Feinberg says that the latrine arrangements impressed him as the most humiliating of all his experiences. The provisions for officers and physicians were far from being any better than for the other prisoners, but their living quarters were separate.

The conditions as to the food at a number of different German and Austrian camps are described in detail. The portions were so inadequate that the men were weak from semistarvation and the guards mocked and jeered at them. Sometimes they were offered an extra portion, and when the men flocked with their dishes, the guards set the dogs on them and laughed as the dogs bit them. At the Altengrabow camp it is said that the vegetables for the soup, boiled without peeling, were not cleared of dirt and manure. The physicians had to stand in line with the other prisoners to get their vegetable soup or rare herring and potatoes dinner, but Dr. Feinberg relates that he finally secured a larger dish, and the physicians took turns, one getting the food for them all and bringing it to their quarters to eat.

Nikolsky is convinced that it is the deliberate policy of the Germans to undermine the health of the war prisoners so that when they return home they will be unfit not only for further military service but unfit even for self-support as citizens. They are set at tasks that tax the strength of the most robust, such as draining the swamps in northern Prussia and Schleswig, and doing caisson and diver work in building breakwaters in the Baltic.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending May 10, 1918

		Last Week
1. ANNUAL ADMISSION RATE PER 1,000 (disease only):		
All Troops	1,335.5	1,109.7
National Guard Camps	917.3	994.
National Army Camps	1,659.5	1,222.4
Regular Army	1,148.2	1,054.1
2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:		
All Troops	40.8	39.1
National Guard Camps	37.7	35.6
National Army Camps	46.7	43.8
Regular Army	37.	37.4
3. ANNUAL DEATH RATE 1,000 (disease only):		
All Troops	5.3	6.3
National Guard Camps	2.8	3.6
National Army Camps	6.	6.3
Regular Army	5.9	8.19

NEWS OF THE CANTONMENTS

Camp *Zachary* Taylor, Lincoln Division (Eighty-Fourth) Louisville, Ky.

May 20, 1918.

MEDICAL EXAMINATIONS FOR OVERSEAS DUTY

In keeping with the plans of the War Department a board of medical officers is conducting physical examinations of soldiers for oversea duty with the idea of separating those who are *fit* and *strong* enough for foreign service from those that are *just* able to stay in this country for home service.

The first results of these medical boards has just been announced. Those men who have been found physically unfit for oversea service have been carefully examined by seven different boards, and finally by the general reviewing board. The order announcing the list also transfers all of the men to duty with the 159th Depot Brigade, which in army circles is considered an organization that will remain at the camp as a replacement unit for the duration of the war.

REFUSAL TO SUBMIT TO SURGERY

Two soldiers who faced a court martial at the camp for refusing to submit to a surgical operation have changed their minds and have undergone the operations and are doing nicely, according to medical officers. The two soldiers had refused to submit to the operation after a board of medical officers had decided that both should undergo the operations to better fit them for military service.

The Judge-Advocate of the Army recently ruled that where a soldier refused to take medical treatment or submit to an operation after a board had decided that it was necessary he was subject to trial by court martial. The matter has been watched closely at the camp, and staff officers declare that whenever a soldier in the future refuses either medical treatment or operation, after all military regulations are complied with, he will be tried by a general court martial.

FUNERAL EXPENSE

Recent orders from Washington state that if a soldier dies in the military service the United States shall, on written application, pay the reasonable funeral expenses, including the expense of burial and the return of the body of the deceased to his home under the condition that the sum does *not* exceed $100.

TRAINING IN CONVALESCENT HOSPITAL

The infirmary will be under the *direct* jurisdiction of
Lieut.-Col. Will L. Pyles, commanding officer of the hospital,
but Lieut. Sites of the One Hundred and Fifty-*Ninth* Depot
Brigade has been *designated* as the *officer* in charge of the
military instructions of the patients. The idea is to prevent
as *far as possible, loss of time in army* training. Electric
buzzers are being installed so that the patients may be taught
telegraphy. They will be instructed in *wigwag* and sema-
phore signaling, receive lectures *on military* subjects, and
those whose conditions will permit will be drilled.

The *patients* will be classified into four groups. The first
group will consist of the resting cases. They will walk *to*
the mess hall for meals and receive lectures. The second
group will be made up of those able to take light exercise.
They will go out on short walks, accompanied by medical
officers. The third group will include those able to drill.
The drill *periods* will be of short duration, probably a half
hour at a time.

The fourth group will be known as the reconstruction class. Men coming into the Army through the selective draft who are found *to have slight physical* defects will be assigned to this section with a view of building them up so that they will be elegible for general military service. Special physical exercise will be *prescribed for each individual case* to meet the needs. As an illustration, a man having foot trouble will be given exercise to strengthen his feet, and a man having slight heart weakness will be given a different exercise tending to improve the heart muscles.

This system was tried out at other camps and found to be *beneficial.* Many recruits were reclaimed for the Army that otherwise would have been lost to the fighting forces. Good results are expected here.

PROMOTIONS

The following officers have been recommended for promotion as lieutenant-colonels: WALTER BENSEL, WEBSTER CALVIN, New *York City; DAVID B. DOWNING,* Detroit, Mich.; CHANNING FROTHINGHAM, Boston, Mass.; HERBERT I. HARRIS, Fort Con*stitution, N. H.; RUSSELL R. JONES,* Pittsburgh, Pa.; STEWART R. ROBERTS, Atlanta, Ga.; CHARLES H. TAIT, Philadelphia, Pa.; RAYMOND C. TURCK, Jacksonville, Fla.

Officers of the Medical Reserve Corps Recommended for Promotion as Majors, Since March 1, 1918

HENRY ABRAHM, San Francisco, Calif.; GEORGE CUMMINGS ALBEE, South Orange. N. J.; JAMES S. ALLEN, Geneva, N. Y.; ROBERT A. ALLEN, *Tacoma, Wash.; CURTIS ATKINSON, Fort Collins, Colo.; WILLIAM HUPP BALDWIN,* Memphis, Tenn.; FRANK MILAN BARNS, Harrison, Neb.; RICHARD BEW, Atlantic City, N. J.; GILBERT W. BREHM, Columbus, Ohio; BENJAMIN HENTON BROWN, Muskogee, Okla.; THOMAS A. BURCHAM, Des Moines, Ia.; *BURTON CHANCE,* Philadelphia, Pa.; WALDEMAR A. *CHRISTENSEN, Douglas, Ariz.;* ELBERT CLARK, Chicago, Ill.; WILLIAM A. CLARK, Trenton, N. J.; *CLARENDON J. COMBS,* Oshkosh, Wis.; CLINTON W. D'ALEMBERTE, Pensacola, Fla.; THOMAS C. DAVISON, Atlanta, Ga.; FRANK DEACON, Chicago, Ill.; WALTER A. DOMER, Wabash, Ind.; LUCIUS FRANCIS DONOHOE, *Bayonne,* N. J.; *FRANCIS J. EISEMAN, SUMNER EVERINGHAM,* New York City; ALBERT MARTIN FARRELL, Two Rivers, Wis.; JAMES G. GLYNN, Fort Crockett, Tex.; GEORGE S. FODEN, *Detroit, Mich.;* ALBERT P. FRANCINE, Philadelphia, Pa.; *JOSEPH* C. FRIEDMAN, Chicago, Ill.; EMERY C. GAFFNEY, Lincoln, Ill.; *GEORGE WARREN GARDNER, Providence, R. I.; FRANK WIL*LIAM GEORGE, Worcester, Mass.; ALEXANDER LIDDELL GILLARS, Pottsville, Pa.; DANIEL J. GLOMSET, Des Moines.; HARRY *SEARLS GRADLE,* Chicago, Ill.; ALLEN HAMILTON, Fort Wayne, Ind.; EDWARD L. HANES, Rochester, N. Y.; THEODORE H. *HARRELL, Gonzales, Tex.; ARTHUR HARTLEY, Philadelphia, Pa.;* WILLIAM BROWN HEAGERTY, Mazeppa, Minn.; WILLIAM H. HENGSTLER, *Minneapolis, Minn.; HENRY WILLIAMSON HOAGLAND, Fort Douglas, Utah; CHARLES W. HUGHES,* Winneconne, Wis.; WILLIAM E. KNEWSTEP, Hampton, Va.; JACOB CARL KRAFFT, Chicago, Ill.; HAROLD L. Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

New Officers Elected.—At the forty-seventh annual meeting of the medical society of the state of California, at Del Monte, April 15 to 17, the following officers were elected: president, Dr. Cornelius Van Zwaluwenburg, Riverside; vice presidents, Drs. John H. Graves, San Francisco, and Ferdinand Stabel, Redding; secretary, Dr. Saxton Temple Pope, San Francisco, and delegates to the American Medical Association, Drs. George H. Kress, Los Angeles, Oliver D. Hamlin, Oakland, and Victor G. Vecki, San Francisco. Santa Barbara was selected as the next place of meeting. The association adopted resolutions remitting the dues of members in the military service, and adopted plans for calling on all members of suitable age and otherwise available to tender their services to the government.

Personal.—Capt. Walter O. Howell, San Francisco, on duty at Camp Fremont, fell from a horse, May 23, fracturing his left femur near the hip joint.——Dr. Lewis Michelsen, San Francisco, has been appointed by the San Francisco Board of Health director of the branch office in the Underwood Building, succeeding Dr. Harry G. Irvine.——Dr. Walter Lindley, Los Angeles, who was operated on recently in the California Hospital, is reported convalescent.——Dr. Alfred Guido Rudolph Schlosser, Hollywood, has petitioned the Los Angeles Superior Court to legally change his surname to Castles.——Dr. Howard C. Naffziger has been placed in charge of the division of brain surgery in the Central Reconstruction Hospital, Fort McHenry, Md.——Dr. John W. Hanner has been appointed health officer of Sacramento, succeeding Dr. Gustavus C. Simmons, resigned.——Because of alleged disloyal utterances the New England Society, Oakland, at a recent meeting is said to have voted unanimously for the expulsion of Dr. Heinrich E. Franck from the organization.

COLORADO

Personal.—Dr. J. L. Tadlock, Palisades, has been appointed coroner of Mesa County, succeeding Dr. Arthur G. Taylor, who has entered the military service.——Dr. Edward W. Lazell, Denver, has returned after several months of service in French hospitals.

Licenses Revoked.—At its January meeting, the Colorado State Board of Medical Examiners revoked the license of Dr. Robert Ritchie Walker of Canon City, on the ground that he had been convicted of a crime involving moral turpitude. At its April, 1918, meeting, the board also revoked the license of Dr. Allen R. Ransom of Denver, on the following grounds: For the last seven months of 1917 he had been practicing in Colorado without a license; he had, during the same time, been in the employ of one E. J. Kellihan, who was not licensed to practice medicine in Colorado, and he had practiced as the partner of E. J. Kellihan, with whom he had entered into an agreement promising to divide fees which had been obtained for professional services.

CONNECTICUT

Personal.—After forty years of service, Dr. Charles E. Stanley has resigned as a member of the staff of the Connecticut State Hospital, Middletown, and his resignation is to take effect July 15.——Dr. Thomas F. Keating, Manchester, has recently returned from China where he has been engaged in government sanitary work.

New Home for Society.—The New Haven Medical Society has secured an option on the Townsend property, New Haven, and is raising a fund of $55,000 for the purchase of the property. The house will be used for general headquarters, meetings, and social gatherings, and will contain the library and reading room of the organization. In the near future it is proposed to erect a brick addition to the building as an assembly room.

New State Officers.—At the one hundred and twenty-sixth annual meeting of the Connecticut State Medical Society held in Hartford, May 15 and 16, under the presidency of Dr. Edward K. Root, Hartford, the following officers were elected: president, Dr. Charles J. Bartlett, New Haven; vice presidents, Drs. Frank E. Guild, Windham; James H. Kingman, Middletown; secretary, Dr. John E. Lane, New Haven; treasurer, Dr. Phineas H. Ingalls, Hartford; delegates to the American Medical Association, Drs. D. Chester Brown, Danbury, and John E. Lane, New Haven, and alternates, Drs. Max Mailhouse, New Haven, and Robert L. Rowley, Hartford.

DELAWARE

Honor Veteran Physician.—About fifty physicians of Wilmington gave a complimentary dinner to Dr. Henry J. Stubbs at the Hotel Dupont, April 25, to commemorate his completion of fifty years of active practice.

Personal.—Dr. T. H. Davis, superintendent of the Ferris Industrial School has sent in his resignation, to take effect June 1, and will practice in Wilmington.——Drs. Robert Ellegood and Michael Ostro have been appointed members of the board of health of Wilmington.

State Board Election.—At the annual meeting of the state board of health, held in Wilmington, the following officers were reelected: president, Dr. William P. Orr, Lewes; secretary and registrar, Dr. Abram E. Frantz, Wilmington, and pathologist, Herbert J. Watson, Wilmington.

DISTRICT OF COLUMBIA

"Podiatrists" to Be Licensed in the District of Columbia.—Podiatrists, commonly known as chiropodists and sometimes vulgarly called "corn doctors," can no longer practice their calling in the District of Columbia unrestricted. Congress has just enacted a law forbidding the practice of podiatry in the district except by persons who have passed such examinations concerning their fitness as the health officer of the district may prescribe. The health officer must conduct the required examinations. The law does not prevent licensed physicians from practicing "podiatry," nor podiatrists who have been practicing in the district for not less than one year at the time of the approval of the law. By the law, podiatry is defined as the surgical, medical, or mechanical treatment of any ailment of the human foot, except the amputation of the foot or any of the toes; but the podiatrist may not lawfully use other than local anesthetics.

Medical Society Creates a War Committee.—By resolution adopted May 15, the Medical Society of the District of Columbia constituted its executive committee a war committee. The committee was authorized to send to each active member of the society a questionnaire designed to elicit such information as may be necessary to determine which of the members should perform military service and which should remain at home to care for the civil population. The resolution impresses on the entire membership of the society the duty of responding promptly to the questionnaire, and on those members who may be selected by the war committee for military service, the importance of early applications by them for commissions in the medical service of the Army or the Navy. The entire organization of the society, and its personnel, were by the resolution offered to the American Medical Association to help in the campaign the association has undertaken at the request of the Surgeon-General of the Army and Navy to obtain adequate complements of medical officers for both services.

FLORIDA

Personal.—Horatio M. Parker has been appointed bacteriologist and chemist for the Jacksonville Board of Health.——Stewart G. Thompson, formerly of Kansas City, has taken up his duties as vital statistician of the state board of health.——Dr. Lawrence T. Galphin, Fernandino, has been appointed district health officer of the second district of the state board of health, succeeding Dr. Joseph E. Taylor, resigned.

State Meeting.—At the meeting of the state medical society at Tampa, May 16, the following officers were elected: president, Dr. Frederick J. Walter of Daytona; vice presidents, Drs. William P. Adamson, Tampa; H. Mason Smith, Chattahoochee; acting secretary, to serve during the absence of Dr. Graham E. Henson, Jacksonville, who is serving with the United States forces, Dr. W. H. Coffee, Winter Haven; treasurer and editor of the *Florida State Medical Journal*, Dr. William R. Warren, and delegate to the American Medical Association, Dr. John S. Helms, Tampa. Miami was selected as the next place of meeting.

IDAHO

Personal.—Dr. Susan E. Bruce, city health officer of Lewiston, has been reappointed a member of the state medical board.——Dr. Walter F. Pike, superintendent of the Blackford State Hospital, has resigned.

ILLINOIS

Service Flag Unfurled.—The Auxplaines Medical Society at its annual meeting, April 4, in Oak Park, unfurled a service flag with thirty-one stars.

Tablet to Commemorate First Medical College.—Acting on the advice of the Illinois centennial commission, Morgan County has erected a marker on the site of the first medical college in Illinois.

Personal.—Dr. Charles W. Miller, Peoria, has been appointed special medical health officer for the Camp Herring military zone which embraces the city of Peoria and adjoining townships.——At its annual meeting, May 5, the Illinois Public Health and Welfare Association elected Dr. John A. Robison, Chicago, president, and Drs. Wilbur H. Gilmore, Mount Vernon, and H. Nelson Heflin, Kewanee, vice presidents.

Chicago

Pathologist Wins Prize.—Harry Lee Huber, formerly pathologist in the University of Chicago, was awarded the Ricketts Prize, May 2, on account of his research work to determine new methods of treating tuberculosis. The prize consists of the income of $5,000 and is given in memory of the late Dr. Howard Taylor Ricketts.

College of Medicine of University of Illinois Adopts Quarter System.—The University of Illinois, College of Medicine, announces that beginning with June 3, it will operate on the quadrimester system. In this system there will be three terms of four months each calendar year. The courses will be so arranged that it will be possible for a student to enter the school at the beginning of any one of the three terms.

Personal.—Rollo K. Packard, for the last seven years superintendent of Washington Park Hospital, was given a banquet by fifty-seven of his associates, April 29.——Dr. Homer V. Halbert has been elected president of the Empire State Society of Chicago.——Dr. William H. Burmeister, coroner's physician, has resigned to enter the military service.——Major Kellogg Speed, M. R. C., has been transferred from service with Base Hospital No. 12 to service with the 42d Division of the American expeditionary forces.

IOWA

Personal.—Dr. Walter A. Matthey, Davenport, was operated on at the Augustana Hospital, Chicago, for disease of the gallbladder.——Dr. Eli Grimes has assumed charge of the Des Moines Tuberculosis and Free Public Health Nursing Association.——Dr. Jay Crowley, Rock Rapids, is reported ill with scarlet fever.

New Officers.—At the meeting of the State Society of Iowa Medical Women, held at Fort Dodge, May 7, the following officers were elected: president, Dr. Jeanette F. Throckmorton, Chariton; vice presidents, Drs. Josephine M. W. Rust and Sarah A. Kime, Fort Dodge, and Rosa E. Lowder, Maquoketa; secretary, Dr. Nelle S. Noble, Des Moines, and treasurer, Dr. Jessie B. Hudson, Carroll.

LOUISIANA

Officers Elected.—At the thirty-ninth annual meeting of the Louisiana State Medical Society, held at New Orleans, April 16, 17 and 18, the following officers were elected: president, Dr. Wilkes H. Knolle, New Orleans; vice presidents, Drs. G. M. G. Stafford, Alexandria; Amedee Granger, New Orleans, and Albert E. Fossier, New Orleans, and secretary-treasurer, Dr. Paul T. Talbot, New Orleans. The following were elected as councilors of the respective districts: Drs. Paul J. Gelpi, New Orleans; Beverly W. Smith, Franklin; Joseph E. Knighton, Shreveport; Jesse L. Adams, Monroe; James J. Robert, Baton Rouge; E. M. Ellis, Browley, and Eugene L. Henry, Lecompte.

MARYLAND

Physician Convicted.—Dr. Chauncey T. Scudder, proprietor of a sanatorium at Arlington, is said to have been found guilty of furnishing morphin to an addict in violation of the federal law and to have been sentenced to imprisonment for three months.

Antituberculosis Association Meeting.—At the meeting of the state War-Time Tuberculosis Conference held in Baltimore, April 18, Dr. Henry Barton Jacobs, Baltimore, was elected president, Dr. C. Hampson Jones, vice president, and Drs. John S. Fulton, William T. Howard, Martin F. Sloan, William S. Thayer, Thomas Fell, J. Hall Pleasant, Roland Park, and Allen K. Krause were elected members of the executive committee.

Personal.—Dr. William N. Gassaway of Ellicott City has been appointed chief health officer of Howard County.——Dr. Winford H. Smith, superintendent of the Johns Hopkins Hospital, who has been working in the office of the Surgeon-General of the Army in Washington for the past ten months, has been commissioned a colonel in the medical corps.——An informal reception was given, May 14, in the chapel of Brown Memorial Church to Dr. Mildred Jenks, who will sail this summer for Canton, China. Dr. Jenks goes out as the representative of the Women's Missionary Society of Brown Memorial Church and will be resident physician at the David Gregg Hospital for Women and Children in Canton.——Dr. Stanley Mitchell has been appointed medical superintendent of the Franklin Square Hospital, succeeding Dr. W. Todd Turnehough, resigned to become chief surgeon of the Dupont Mills, Parrin, N. J.

MASSACHUSETTS

Free School on Public Health.—A free school on public health with sessions, May 28, 29, 30 and 31, has been arranged for by the committee on public health of the Massachusetts Medical Society in cooperation with the state and federal public health organizations. Among the subjects for discussion are water and sewage, public health laboratory, public health reports, specific diseases, industrial hygiene, child welfare and public health administration. On the evening of May 30 in Boston, Dr. W. W. Peters will lecture on "Public Health Education in China." Some of the best known men in public health work will address the various sessions.

Personal.—Dr. Richard C. Cabot, Boston, now in France as a member of Base Hospital Unit No. 6, has been made a full professor in Harvard University.——Dr. Edwin A. Locke has been appointed assistant professor of medicine in Harvard Medical School.——Dr. Algernon Coolidge has been appointed acting dean of the Harvard Graduate School of Medicine, succeeding Dr. Alexander S. Begg, Boston, now on duty with the U. S. Army.——Drs. Kallman M. Davidson, Albert Ehrenfried and Harry Linenthal, Boston, and Louis M. Friedman, New York, have been appointed the executive committee of the reorganized medical board of the Beth Israel Hospital, Boston.——Dr. Louis Lazarus, Worcester, was seriously injured in an automobile accident, April 21.

Secretaries for Physicians.—Following an inquiry among physicians as to the desirability of establishing a course for the special training of secretaries for physicians, Simmons College adopted a course of training for that purpose and in June the first class will complete the course. The course includes technical secretarial work, such as stenography, typewriting, filing, cataloguing and bookkeeping, and in addition, familiarity with the medical vocabulary, some language training and abstracting, courses in general chemistry, bacteriology and applied routine medical laboratory work. It is believed that these secretarial technicians will prove useful to hospitals, clinics and specialists who may have certain routine laboratory work, such as urine and blood analysis, culturing, and microscopic examination of pathologic specimens.

Meeting of Examining Physicians.—At the meeting of the Massachusetts Society of Examining Physicians at Lynn, April 26, the society voted to oppose the bill in the state senate which proposes to give the reeducation and rehabilitation of injured industrial workers to the state board of education. It was the sense of the society that such power should be conferred on the industrial accident board. The society elected the following officers: president, Dr. Frank E. Schubmehl, Lynn; vice presidents, Drs. Herbert H. Howard, Boston; Charles S. Benson, Haverhill; John E. McCartin, Boston; secretary, Dr. James H. Stevens; treasurer, Dr. John S. Phelps, and councilors, Drs. Frederick J. Cotton, Boston; Jonathan F. Edgerly, Lincoln; William P. Coues, Boston; Francis J. Hanley, Whitman, and Robert C. Gwin, Boston.

MINNESOTA

Ohage Resigns.—Dr. Justus Ohage, health officer of St. Paul for twelve years, resigned, April 19, after a hearing in the mayor's office, in which he refuted charges of disloyalty that had been brought against him.

MISSOURI

Conference on Military Medicine.—Under the auspices of the St. Louis Medical Society, the medical officers at Jefferson Barracks and the deans of the Washington and St. Louis Universities, a clinical conference on military medicine will be held in St. Louis, June 5, 6 and 7, with headquarters at the building of the St. Louis Medical Society, 3525 Pine Street. On the first day, the members will be escorted to Jefferson Barracks, where the surgeons will arrange for a general inspection of the post, drills, demonstrations at the examination barracks, and lectures on sanitation and infectious diseases. On the following days, clinical programs and lectures have been arranged at the Washington and St. Louis universities and at various city institutions. The object of the meeting is the immediate enrolment of physicians in the Medical Reserve Corps of the Army. Those expecting to attend are requested, at the earliest possible date, to notify the president of the St. Louis Medical Society, 3523 Pine Street, St. Louis.

NEW YORK

For Protection of Watershed.—Governor Whitman has signed the bill passed in the legislature for the protection of the Croton watershed from which the water supply of New York City is derived. This bill aims to prevent pollution of the watershed by state institutions which are to be established in the water collecting area. The sites for the New York State Training School for Boys and the Mohansic State Hospital, Yorktown, will be located elsewhere.

New York City

New Traffic Rule for Physicians.—The first of several new traffic rules which Deputy Commissioner John A. Harris is planning to put into effect this month became operative, May 15. This ordinance authorizes the issuing of special cards to physicians, which will permit their motor cars to stand in crowded streets when on urgent medical calls.

Personal.—Dr. Antoine Depage has embarked for this country and expects to arrive at an American port within a few days.——Dr. Alexis Carrel of the Rockefeller Institute has been promoted by the French government to the rank of commander of the legion of honor.——Dr. Benjamin T. Terry has resigned his position as director of the Brooklyn Laboratories of Pathology.

Army Takes Sea-View Hospital.—An agreement was reached, March 15, between Health Commissioner Royal S. Copeland, Mayor Hylan and Lieut.-Cols. Hornsby and Kramer, under which the army will take over Sea-View Hospital, which has been conducted as a home for tuberculosis patients. The government will take possession as soon as the patients can be removed to the city's hospital at Otisville, N. Y., where the Army has agreed to erect additional buildings for the city.

Commissioner Copeland Confers with Federal Health Officials.—A conference was held, May 15, between Dr. Royal S. Copeland, the new health commissioner of New York, and Surg.-Gen. Rupert Blue of the Public Health Service, Acting Surg.-Gen. Col. James W. Furbush of the Army, and Surg.-Gen. William C. Braisted of the Navy, as a result of which the health department has announced its intention of giving its full cooperation to the national health service. The federal authorities have been assured that there will be no lowering of the standards of health conservation in New York. It was distinctly stated by Dr. Copeland that the policy of disorganization, retrenchment and the substitution of talent of lesser efficiency would not be permitted to continue.——Commissioner Copeland has announced the appointment of Dr. S. Dana Hubbard of the department of epidemiology, to take charge of the bureau of public health education temporarily, after May 15, when Dr. Charles F. Bolduan's resignation goes into effect. He has also appointed a committee consisting of Dr. Louis I. Harris, head of the bureau of preventable diseases; Dr. Alonzo Blauvelt, assistant sanitary superintendent, and Dr. B. Franklin Knause, Brooklyn, deputy health commissioner, to investigate and report on the handling of industrial sanitation in the health department itself.

NORTH CAROLINA

Personal.—Dr. Albert Houck, for ten years assistant physician to the Morganton State Hospital, has resigned. The cause of his resignation is said to be his pro-German sympathies and utterances.

Hospital has New Home.—The Presbyterian Hospital, Charlotte, has moved from its old buildings in the business portion of the city to its new home which is located in a 20-acre oak grove. The hospital has seventy private rooms and is thoroughly equipped.

OHIO

Training for Speech Correction.—It is announced that, during the next year, Cleveland will spend $10,000 to install in its public school system instruction in the correction of defects in speech.

Licenses Revoked.—At a meeting held April 2, the Ohio State Medical Board revoked the licenses of Drs. Robert Austin Browne and Frank Llewellyn Bowsher, both of Akron, for extravagantly worded and dishonest newspaper advertising. May 6, for a similar reason, the board also revoked the license of Dr. Franklin Stuart Temple, formerly of Toledo. Dr. Browne had advertised "quick results" for "weak, worn-out men," Dr. Bowsher had advertised himself as "Akron's reliable specialist," and Dr. Temple was proclaiming himself as a magnetic healer and had conducted a public clinic in the opera house at Lorain. Action was taken under the law which makes it illegal for a licensed practitioner to issue advertisements intended, or having a tendency, to deceive and defraud the public.

PENNSYLVANIA

Personal.—Dr. Samuel H. Ensminger, York, who has been ill in Philadelphia with an infection of the arm, has returned convalescent.——Dr. Thomas A. Taylor, Pomeroy, who has been seriously ill, has recovered.——Dr. John A. Fell has been reappointed a member of the Doylestown Board of Health for the twenty-fifth consecutive term.——Dr. Jane R. Baker, West Chester, has been appointed a trustee of the state hospital for chronic insane, Wernersville.——Dr. George W. Neff, Masontown, has been elected president of the board of trustees of the Cottage State Hospital.——Dr. Edwin S. Dorworth, Bellefonte, recently suffered a slight cerebral hemorrhage.

Philadelphia

Obstetric Society Meeting.—The fiftieth anniversary of the Philadelphia County Obstetrical Society was celebrated, May 17. The progress of obstetrics was reviewed and the men eminent in this domain of medicine were pointed out. Photographs of the prominent pioneers of obstetrics and gynecology were shown and their achievements were outlined by various speakers. Addresses were made by Drs. Barton Cooke Hirst, president of the society; Edward E. Montgomery, C. E. Githens, George M. Boyd, Richard C. Norris, B. F. Bear and Edward A. Schumann. Among the guests at the anniversary meeting were several members of the American Gynecological Society, which held its annual meeting also in this city, May 16, 17 and 18, inclusive. Dr. George W. Kosmak, New York, editor of the *American Journal of Obstetrics*, reviewed in abstract the early publications of the obstetric society as published in the *Journal*.

CANADA

Decoration for Medical Officer.—Col. Harvey G. Young, St. Mary's, was recently granted the D. S. O. for establishing an advanced post under a heavy barrage fire and successfully evacuating more than 400 wounded men.

Ten Gallons of Liquor Allowed to Physicians.—By a recent amendment to the Ontario temperance act, it is provided that a physician may keep 10 gallons of liquor in his private house, office or dispensary, despite anything to the contrary which may appear in the act.

New Officers.—At the annual meeting of the Niagara District Medical Association held in Niagara Falls, April 29, Dr. William K. Colbeck, Welland, Ont., was elected president; Dr. Charles E. Duggan, St. Davids, Ont., vice president, and Dr. Harry D. Cowper, Welland, Ont., secretary-treasurer.

Health Bulletin Withdrawn.—The Toronto Academy of Medicine, at its last meeting adopted a resolution expressing regret at the withdrawal of the *Health Bulletin*, issued by the department of health of the city of Toronto and expressing its appreciation of the value of the *Bulletin* to the citizens of Toronto.

Medical Officers for Military Districts.—The medical orders for the Toronto military district have been compiled and approved by Col. H. C. Bickford. The orders furnish complete instruction to the military surgeons and explicit rules relative to soldiers sick while on pass or furlough. Lieut.-Col. Edward S. Ryerson, Toronto, is director of military service; Lieut.-Col. Charles Carter, Hamilton, Ont., is in command of the hospitals; Major G. S. Fowlkes is in charge of the administration of medical service; Capt. S. J. H. Maywood is in charge of medical practice, and Lieut.-Col. John W. S. McCullough is in charge of sanitary work.

Hospital News.—A hospital is to be built in Halifax, N. S., for the American Red Cross. It will be for soldiers and sailors of the United States who may become ill in that port or who may be brought there needing treatment. It will be situated near the Nova Scotia Hospital.——The St. Thomas (Ontario) Medical Association have asked the board of governors of the Amasa Wood Hospital of that city to take the institution out of the hands of the city council, place it in trust, and have its capacity increased.——The board of governors of Notre Dame Hospital, Montreal, intend to build a million-dollar hospital. Construction will be begun before the end of the war.——The Montreal Presbyterian College and the David Morrice Convocation Hall in connection therewith have been handed over to the military for the purposes of a hospital for returned soldiers.

Personal.—Major Kenneth McCormack, C. A. M. C., has had conferred on him the D. S. O.——Capt. Dimrock Stanley Cassidy, R. A. M. C., Winnipeg, is the recipient of the Military Cross.——Lieut.-Col. Robert M. Simpson, Winnipeg, assistant director of medicals, after returning to France, has been gazetted colonel.——Major John E. Coulter, M.D., has been made president of a traveling medical board in England.——Capt. Freer Richardson, of the Canadian Medical Service, London, England, who was in Bagdad in charge of the army hospital, has been transferred to Mesopotamia.——Capt. D. M. Warren resigned recently from the R. A. M. C. and has been granted a commission in the C. A. M. C., and appointed to the King's Red Cross Hospital, Bushey Park, England.——Capt. Donald G. McKay, C. A. M. C., Bradford, Ont., who was gassed while serving in the trenches, has returned to Canada.——Capt. Cleveland Roy Wilson, Toronto, on the staff of the hospital for sick children, is on his way to the front.——Majors J. Cameron Wilson, London, Ont.; G. C.

Halle and John G. Hunt, Fort William, are returning to Canada. Major Hunt has served with the Russian army in Russia and Roumania.——Surg.-Gen. Henry M. Featherstone, of the Anzacs, is visiting in Ontario, on a tour of the military hospitals, to gain information on the best methods of handling the returned soldier problem so as to apply them in Australia.

GENERAL

Climatologists Meet.—The thirty-fifth annual meeting of the American Climatological and Clinical Association will be held in Boston, June 5 and 6, under the presidency of Capt. J. Elliott, C. A. M. C., Toronto, Ont. The session of the association will be held at the Boston Medical Library, the Fenway.

Coming Meetings.—The American Public Health Association will hold its next meeting in Chicago, from October 14 to 17, inclusive. The principal topic of the meeting will be "The Health of the Civil Population in War Time."——The National Tuberculosis Association, under its new name, will meet in Boston, June 6, 7 and 8. The headquarters will be at the Copley-Plaza Hotel.

More Nurses for the Navy.—The Committee on Public Information, division on woman's war work, issues the following: The Nursing Corps of the United States Navy is cooperating with the Red Cross in its drive to increase the enrolment of nurses. Secretary Daniels appeals to the women of the country to aid this branch of national defense by offering their services and taking advantage of the facilities for training offered during the summer by the Vassar Training School for Nurses.

Teaching Fellowships Available.—It is announced that a number of teaching fellowships in pediatrics are open to students in the University of Minnesota Graduate School, to which a stipend of $500 for the first year is attached, the amount being increased later. Men above the draft age will be taken, and a splendid opportunity is afforded to men who wish to make a specialty of pediatrics. Further information about these fellowships may be obtained from Dr. Julius P. Sedgwick, head of the department of pediatrics, University of Minnesota.

Conference of Public Health Officials to Be Held in Washington.—The annual joint conference of the United States Public Health Service with state and territorial health officers, will be held in Washington, June 3 and 4. The sanitation of extracantonment areas will be one of the chief subjects on the program. Reports will be made as to the success of the cooperative arrangement developed during the past year for preventing the interchange of disease between civil and military populations. Among the subjects to be discussed are the relation to public health of industrial hygiene and sanitation, especially in war industries; the care of the health of tuberculous soldiers on their return to civil life; the use of records of drafted men for public health purposes; effects on the public health of the forthcoming shortage in the medical profession. Among the subjects not so closely related to the war are: the securing of better morbidity reports, and the question of pure water supplies for railroads. There will be reports of standing committees in regard to many of the subjects outlined above and in regard to the sanitation of public conveyances, rural sanitation, and increasing the efficiency of the conferences. The sessions will constitute the sixteenth annual conference of state and territorial health authorities with the United States Public Health Service.

FOREIGN

Asylum for Orphans of Physicians in Spain.—About a year ago the authorities in Spain decreed the foundation of an orphan asylum for orphans of physicians. The plan included the compulsory organization of the profession throughout the country into district *colegios medicos,* and also the use of a stamp to be affixed to all medical certificates, death notices and similar papers to be made out by physicians. The expense of the stamps is to be borne by the patient or his family, except in the case of paupers, for whom special provisions are made. The orphan asylum is to be known officially as the Colegio de huerfanos de la clase medica, or the Colegio del Principe de Asturias. The building for the purpose is nearly completed.

Physicians in the Spanish Parliament.—The *Siglo Medico* expresses regret that so few physicians seek to be nominated to the lower house. With a little effort, the profession could have a strong representation in the Chamber of Deputies, and could influence public health legislation. In the senate, the profession is well represented as there are a number of physicians who are life members, and the ex-ministers are ex-officio members ,while the universities are entitled to elect a representative to the senate, and also the Real Academia de Medicina. The latter has recently selected Dr. L. O. Morejon for this position, and the Universidad Central has elected Dr. A. Espina, one of the editors of the *Revista de Medicina y Cir. Practicas.*

CORRECTION

Chicago News.—Last week, it was stated that Dr. Haim I. Davis had been appointed assistant physician of the county psychopathic and detention hospital. This should have been attending physician.

LONDON LETTER

London, April 30, 1918.

Saving the Wounded in the Retreat

During the German advance in the present offensive, the evacuation of the dressing and clearing stations was a difficult task. They were situated as far forward as Ham, Cagny and Noyon in the Fifth Army area, and at Tincourt, Ytres, Grevillers, and Achiet-le-Grand in the Third Army area. That at Ham fell back to Villers-Carbonnel, but was able to stay there only one day, for already Villers-Carbonnel was under shell fire, and it was obliged to take to the road again to Amiens, and thence again to fall farther back. The hospitals at Cagny and Noyon, owing to the interruption of the railway and roads, could not fall back in the army area, and had to go southward into French territory to the region of Compiègne. By the evening of the first day the hospitals at Tincourt and Ytres were on the move. That at Crevillers was evacuated on the second day. At Achiet-le-Grand, where two hospitals were located on the night of the 21st, shells began falling, and in one eight orderlies were killed and the operating theater was destroyed. The hospitals fell back to Puchevillers, only to be bombed there that night. By the second day, therefore, all the clearing stations were back, or moving, to the second line positions, namely, beside those in the French area, at Roye, Maricourt, Edgehill (near Dernancourt) and Aveluy. None of these places, however, afforded more than a temporary resting place, and again journeys had to be resumed to a series of positions farther back. Every patient from every station was got away. The narrowest escape from losing patients was at Roye, where the hospital stayed on till March 26, and then had to go in a hurry, leaving seventy patients behind, with an officer and twelve orderlies to look after them. Some motor ambulances were met, and urged to go back and make a final effort to get the patients off. They did so, and as the last ambulance left with the last batch of patients it was fired on by the advancing Germans with their rifles. The method of evacuation was, as far as time permitted, extremely orderly and thorough, so that as little as possible was left to the enemy. All stations had nursing sisters on their staffs, and one sister was killed and one wounded. The regular procedure was, however, for the nurses to be moved first on an ambulance or lorry. Then every patient who could walk had to take the road on foot. The severely wounded were loaded on ambulances, and the staff then turned to the work of destruction or salvage before following. The huts in most cases were destroyed, the tents either taken away or burned. All medical stores and appliances, roentgen-ray apparatus, etc., were saved; only some heavy things, such as sterilizing plants, being impossible to move, as well as iron beds and in some cases bedding were left. All surgical instruments were, it is believed, saved, the medical officers in several instances having to put them on wheeled stretchers and trundle them along the roads at night. Some were so worn out with the ceaseless care of wounded and marching that they swayed about the road like drunken men. A clearing station is practically a hospital with from 1,000 to 1,500 beds, and therefore impossible to remove in a few hours; but an organization has been perfected by which a portion constituting a complete unit of 200 beds, with patients, staff and appliances, can be moved immediately on a very small number of lorries. Ahead of the general exodus went this selected portion, which was established and already at work on a new site before the later detachments arrived. So there was a minimum disarrangement in the care of the wounded, and at the end, when all the hospitals finally reached the rearmost positions, the wounded appeared not to have suffered at all, but would have been regarded as good cases, measured by the standard of ordinary batches as they come from the battlefield.

The Treatment of Shell Shock

The large number of men discharged from the army because of shell shock presents a new problem. They have been treated in a long series of military hospitals, where every effort has failed, and finally they have been sent out into the world physically sound but mentally broken down, incapable of work and unfit even to go home to their families. Like many other new problems presented by the war, experience and energy have solved this one. Special hospitals have been established for the treatment of such men with excellent results. The patient is first put to bed in a room alone and the physician brings mental influence to bear on him, for drugs are of little use. He is encouraged to regain his lost will power. The next step is to put him in a room with suitable companions and rouse his interest in things outside himself. At first he is very unsociable because he has lost self confidence; but sooner or later he begins to mix with his fellows and then plays billiards, cards, or other games. In the gymnasium, systematic exercises are then performed under an instructor. Various forms of work, of which carpentry and bootmaking are the most popular, are next undertaken. At first the patients work only an hour in the day, then two, and so on until six hours are attained. Other trades taught are engineering, electric light work, motor construction, and intensive gardening. Two thirds of the patients return to their former work, and one fourth are made useful workers in some other line. Thus complete recovery takes place in eleven out of twelve cases.

Prosecution for Quackery Under the Venereal Diseases Act

For the first time in England, unqualified persons have been prosecuted for quackery. Until the passage recently of the act for the prevention and treatment of venereal diseases, any quack or nostrum vender was at liberty to advertise his claims to treat any disease with impunity. But when the government decided to go to the expense of providing free treatment for venereal diseases, it also decided not to tolerate the competition of quacks, and made it illegal for unqualified persons to profess to treat them, though they still have full play as regards other diseases. James Walker, Harry Key and Fred Waite were convicted before two justices for advertising in a public urinal to treat venereal diseases. A handbill to this effect in the name of the "Curtis Medical Laboratory" of Hill Street, Birmingham, was found affixed to the wall. Waite, who described himself as manager of the company, had his attention drawn to the bill by a police officer. He said that "those things were in the hands of the advertising agents and they had it in their power to carry everything out"; but he declined to give their names. The defendants were convicted, and fines of $250 were imposed. An appeal against the conviction was made and the case came before three judges. The lawyers for the defense contended that there was no evidence that any of the three had committed the offense. The appeal was dismissed.

A Sexual Offenses Bill

Lord Beauchamp has introduced into the House of Lords a sexual offenses bill which makes it an offense punishable by two years' imprisonment for any person suffering from venereal disease in a communicable form to have, to solicit or to invite intercourse with another person, or wilfully to communicate such disease to another person, provided that no one shall be convicted who proves reasonable grounds for believing that he or she was free from communicable disease at the time. To ascertain whether any person, convicted of any offense, which under this clause would be caused or aggravated by the existence of communicable venereal disease, is in fact so suffering, the court may order the offender to submit to medical examination. If the offender is a female she can elect to be examined by a woman physician. False accusations are punishable by heavy fines or imprisonment. Clause 2 forbids prostitutes and night walkers to loiter in thoroughfares for prostitution or solicitation. Clause 3 stiffens the penalties against brothel keepers and the like. Clause 4 imposes a fine for allowing premises used for public entertainment to be the habitual resort, for whatever purpose, of reputed prostitutes. Another clause forbids the display or transmission of any picture or printed or written matter of an indecent or obscene nature, including any advertisement which relates to venereal disease, nervous debility, or other complaint arising out of or relating to sexual intercourse or which suggests directly or indirectly, either the taking of anything for the purpose of procuring abortion or the use of any premises for an immoral purpose.

PARIS LETTER

Paris, April 18, 1918.

Special Commission for Surveillance of Outcome of Nervous and Mental Disease in Soldiers

Conforming to the plan adopted December, 1917, at the reunion of the chiefs of the centers of neurology and psychiatry and by the Société de neurologie, the undersecretary of state for the Service de Santé militaire has decided on the creation of a special commission for supervision of the results of treatment of nervous and mental disease in soldiers. This commission is charged with the technical control of the neurology and psychiatry centers, and also the solution of medicolegal questions in debatable and rebellious neurologic or psychiatric cases (convalescence, temporary or permanent invaliding, military sanctions, etc.). The committee is called to functionate principally for cases treated in the special centers for functional reeducation and exceptionally for other cases which will be submitted by the undersecretary of state for the Service de Santé militaire. As a rule, the commission will examine on the spot the cases referred to them. The commission is composed of Drs. Achille Souques, médecin des hôpitaux de Paris, Ernest Dupré, professor agrégé à la Faculté de médecine de Paris, et médecin des hôpitaux, Henri Claude, professor agrégé à la Faculté de médecine de Paris et médecin des hôpitaux, and Dr. Froment.

Assignment to Their Home Cities of Physicians in Army Service

As a general rule, mobilized physicians should not be assigned to their home cities. This is merely a matter of justice; it would be unjust if these doctors in military service were stationed in their home town and allowed to continue with their civil practice. This would be greatly to the disadvantage of colleagues mobilized elsewhere. An exception to this rule was, however, made recently in favor of the doctors of the classes of 1887 and 1888 (i. e., those 50 and 51 years of age). However, inasmuch as this privilege has given rise to abuses, the undersecretary of state for the Service de Santé militaire has decided that in order to avoid future abuses: 1. No doctor is to come back to his own city, unless there is a vacancy in his grade. 2. Each assignment shall involve the departure of one physician from the place; no service shall be created, no service shall be divided for the purpose of creating a new post, except when new necessity arises for doing so. 3. Each doctor designated for the civil population of his home town shall be given an unlimited furlough, without pay, unless at the same time he should happen to be in charge of a sanitary formation service or of a *corps de troupe.*

Remuneration for Interns

In conformity with a report made by M. Henri Rousselle, member of the city council, the municipal council of Paris has decided that beginning with January, 1918, and ending with the war, the pay of hospital interns and pharmacists shall be increased by 1,000 francs ($200).

Prize Awarded by the Paris Faculty of Medicine

The council of the Faculté de médecine has decided to award the Chateauvillard prize for 1918 to Dr. E. Velter, the author of a work on war surgery, "Penetrating Wounds of the Head by War Projectiles." Dr. Velter is a former intern of the hospitals of Paris, chief of the laboratory of clinical ophthalmology of the Faculty. This article had already received the Godard prize for 1917 of the Academy of Medicine.

Evening Consultations for Venereal Disease

The municipal council of Paris has decided to institute at l'hôpital Saint Louis a service for evening consultations for venereal diseases. A sum of 20,730 francs has been appropriated for the installation and maintenance of this service for 1918.

Thermometer for the Blind

Many kinds of apparatus may be had which enable the blind to do with their fingers what those who can see do with their eyes. To date, no "digital" thermometer, that can be read with the fingers, has been invented. A number of blind men have entered on the practice of professions in whose pursuit it is necessary to know the exact temperature record. Therefore, the Association Valentin Haüy pour le Bien des aveugles (9, rue Duroc, Paris) has offered a prize of 1,000 francs for the best apparatus which will enable the blind to read temperatures.

Deaths

Capt. Richard Lawrence Jett, M. R. C., U. S. Army, Cleveland; Jefferson Medical College, Philadelphia, 1907; aged 32; formerly a member of the Ohio State Medical Association; a member of the medical staff of the Babies Dispensary and Hospital, Cleveland, was killed in action, April 13. In 1905, he became a member of the British field hospital for Serbia, where he was commended for his bravery during the Serbian retreat, and commissioned captain in the Serbian army; later when the war broke out between America and Germany, he returned to this country and was commissioned a captain in the Medical Reserve Corps, becoming attached to the British expeditionary forces in France; later he was appointed a medical officer of the battalion and had just been cited for three decorations in connection with his work in Serbia.

Died in the Service
IN FRANCE
Capt. Richard L. Jett, M. R. C., U. S. Army, 1886-1918

Isaac Adler, New York City; University of Heidelberg, Germany, 1871; aged 68; formerly a Fellow of the American Medical Association; a member of the Association of American Physicians, the American Gastro-Enterological Association, the New York Neurologic Society, the American Association of Pathology and Bacteriology, the New York Pathologic Society, the American Society of Clinical Investigation and the New York Academy of Medicine; professor of clinical pathology at the New York Polyclinic Medical School; consulting physician to the Polyclinic, German, Beth Israel and People's hospitals, and to the Montefiore Home; died at his home, May 4.

Benjamin M. Worsham, El Paso, Texas; University of Louisville Medical Department, 1886; aged 55; a Fellow of the American Medical Association; a member of the El Paso Civil Service Commission; assistant superintendent of the State Lunatic Asylum, Austin; superintendent of the Southwestern Insane Asylum, San Antonio; superintendent and later supervisor of construction of the State Epileptic Colony, at Abilene; died suddenly at his home, May 2, from heart disease.

Died in the Service
IN FRANCE
Lieut. John D. Arnett, M. R. C., U. S. Army, 1889-1918
(*See The Journal, May 18, p. 1484*)

Capt. Henry Clement Welker, M. R. C., U. S. Army, Norristown, Pa.; University of Pennsylvania, Medical Department, Philadelphia, 1906; aged 38; formerly a Fellow of the American Medical Association; formerly director of the roentgen-ray laboratory at the Episcopal Hospital, Philadelphia; on duty with Base Hospital Unit 34, of the Episcopal Hospital; was brought home, ill, from France, to Washington, D. C., and died at the Government General Hospital, May 1.

Capt. Richard C. Hill, M. R. C., U. S. Army, Irondale, Wash.; Cincinnati College of Medicine and Surgery, Cincinnati, 1892; Medical Faculty of McGill University, Montreal, 1906; aged 50; a member of the Royal College of Surgeons, England, in 1906; a member of the Washington State Medical Association; died, April 18, following an operation.

Major Thomas Connally Cowan, C. A. M. C., London, Ont.; Trinity Medical College, 1883; University of Toronto Medical Department, 1892; formerly president of the medical board of the London mobilization center; he was active in military work and former commanding officer of the 15th Field Ambulance; died at his home, May 5.

Capt. Albert Leslie Grubb, M. R. C., U. S. Army, Berkeley Springs, W. Va.; Barnes Medical College, St. Louis, 1903; aged 37; a Fellow of the American Medical Association; died, March 30, from acute dilatation of the heart, while aboard an Atlantic liner, en route to France, with a contingent of American soldiers.

Walter E. Reily, Fulton, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1896; aged 47; a member of the Missouri Institute of Homeopathy, American Institute of Homeopathy; a member of the American College of Surgeons; died at his home, about May 2, from pneumonia.

Henry Merryman Wilson, Baltimore; University of Maryland, Baltimore, 1850; aged 89; a Fellow of the American Medical Association; formerly served as president and secretary of the Medical and Chirurgical Faculty of Maryland; died at his home, May 8, from senile debility.

Lieut. John Raymond Wood, M. R. C., U. S. Army, Hallock, Minn.; Hahnemann Medical College and Hospital, Chicago, 1911; aged 30; a Fellow of the American Medical Association; died, February 3, from pneumonia, at the base hospital, Fort Sam Houston, Texas, where he had been on duty.

Henry Normanton Chapman, St. Louis; Missouri Medical College, St. Louis, 1893; aged 51; a Fellow of the American Medical Association; a member of the St. Louis Pediatric Society; formerly a member of the St. Louis Board of Health; died at his home, April 25, from heart disease.

Simen Menno Yutzy, Ann Arbor, Mich.; University of Michigan School of Medicine, Ann Arbor, 1891; aged 61; instructor in osteology and demonstrator of anatomy in the University of Michigan; a specialist in diseases of the ear, nose and throat; died at his home, May 3.

Gustav Adolph Heidner, West Bend, Wis.; Rush Medical College, Chicago, 1888; aged 54; a member of the State Medical Society of Wisconsin; a charter member of the Wisconsin Surgical Society; founder of the Heidner Hospital, West Bend; died at Long Beach, Calif., May 3.

Addison Fitzhugh Sanders, Cincinnati; Miami Medical College, Cincinnati, 1898; aged 52; a Fellow of the American Medical Association; a member of the American Academy of Ophthalmology and Oto-Laryngology; was instantly killed, May 5, by being struck by an automobile.

Thomas Hollingsworth Andrews, Philadelphia; Jefferson Medical College, Philadelphia, 1864; aged 74; a veteran of the Civil War; surgeon to the outpatient department of the Pennsylvania and Howard hospitals, Philadelphia; died at his home, May 8.

William O. Ensign, Rutland, Ill.; Wooster Medical College, Cleveland, 1869; aged 76; a Fellow of the American Medical Association; a member of the American Association of Railway Surgeons; a veteran of the Civil War; died at his home, May 8.

Rowland A. Postle, Ashville, Ohio; Medical College of Ohio, University of Cincinnati, 1884; aged 59; formerly a Fellow of the American Medical Association; died at the Hawkes Hospital, Columbus, Ohio, April 30, following an operation.

Charles Ogden Cartwright, Sacramento, Calif.; University of Michigan Medical School, Ann Arbor, 1889; aged 58; a member of the Medical Society of the State of California; died at the Krull Hospital, Sacramento, May 2, from paralysis.

David Gilbert Yates, New York City; New York University Medical Department, 1898; aged 47; a Fellow of the American Medical Association; a member of the American

Laryngological, Rhinological and Otological Society; a member of the New York Academy of Medicine; died at his home, May 9.

William Lewis Brosius, Gallatin, Mo.; Missouri Medical College, 1890; aged 64; a Fellow of the American Medical Association; a member of the American Roentgen Ray Society; formerly health officer of Daviess County; died in his office, April 18, from neuralgia of the heart.

George W. Bliss, Valley Springs, S. D., Hamlin University, Medical Department, Minneapolis, 1895; aged 49; a Fellow of the American Medical Association; for many years president of the school board; died at the Luverne Hospital, Luverne, Minn., April 29, from pneumonia.

Major John Henry Ratz, Preston, Ont.; University of Toronto, Faculty of Medicine, 1895; aged 48; was chief of the medical staff of the board of pension commissioners; formerly with Canadian Expeditionary Forces; died at his home, February 11, from myocarditis.

William Henry Manser, Burden, Kan.; Medical College of Ohio, University of Cincinnati, 1884; Kansas City Medical College, Kansas City, Mo., 1889; aged 59; a Fellow of the American Medical Association; died in St. Mary's Hospital, Winifred, Kan., April 23.

James Rundlet May, Portsmouth, N. H.; Jefferson Medical College, Philadelphia, 1866; aged 76; a retired officer of the United States Navy; he formerly served on the pension board and the school board of Portsmouth; died at his home, April 22.

Charles William Groetsch, New Orleans; Tulane University, Medical Department, 1903; aged 41; formerly a member of the city board of health, and assistant coroner for the parish of Orleans; died in the Touro Infirmary, New Orleans, May 7.

William James Hennessy, Palmyra, N. Y.; Syracuse University, Medical College, 1881; aged 61; a Fellow of the American Medical Association; health officer of Wayne County; died in the Lyons Hospital, Lyons, N. Y., April 27.

John Alexander Vincent, Springfield, Ill.; Eclectic Medical Institute, Cincinnati, 1868; aged 87; once mayor of Springfield; formerly a member of the Illinois General Assembly and of the state board of health; died at his home, May 16.

Reuben Wilson Walters, Chagrin Falls, Ohio; Cleveland Homeopathic Hospital College, 1873; Western Reserve University, Medical Department, 1867; aged 79; a veteran of the Civil War; died at his home, April 19, from pneumonia.

Major John Hastings Bell, M. R. C., U. S. Army, Arkadelphia, Ark.; Beaumont Hospital Medical College, St. Louis, 1892; aged 47; a Fellow of the American Medical Association; died at Fort Sill, Okla., March 4, from erysipelas.

John Chase, Denver; University of Michigan, Medical Department, Ann Arbor, 1881; aged 61; professor of ophthalmology and otology in the University of Colorado School of Medicine; died at his home, May 3, from pneumonia.

George Albert Williams, Brooklyn; New York University, Medical Department, New York City, 1879; aged 63; founder and director of the Bushwick Hospital, Brooklyn; died in that institution, May 11, from pneumonia.

Archibald Campbell, Flushing, N. Y.; Columbia University, College of Physicians and Surgeons, 1871; aged 76; formerly physician at Sanford Hall, Private Asylum, Flushing, N. Y.; died at the home of his brother, May 8.

Henry Dodge Nichols, Douglas, Ariz.; Miami Medical College, Cincinnati, 1897; University of Pennsylvania, Philadelphia, 1898; aged 46; died at the Calumet Hospital, Douglas, April 17, from pneumonia.

Benjamin Prince Earle, Charleston, Ky.; Hospital College of Medical Central University, Louisville, 1889; aged 71; a member of the Indiana State Medical Association; died at his home, May 1, from pneumonia.

Arthur J. Morris, Bloomington, Ill.; Hahnemann Medical College and Hospital, Chicago, 1891; aged 63; a member of the Illinois State Medical Society; died in the Kelso Hospital, Bloomington, April 23.

Thomas Jefferson Patterson, Visalia, Calif., University of California Medical School, 1882; aged 62; a member of the Medical Society of the State of California; died at his home, April 23, from heart disease.

John Andrew Freeman, Crestwood, Ky.; Louisville, Ky., Medical College, 1871; aged 66; a Fellow of the American Medical Association; died at St. Joseph's Infirmary, Louisville, April 26, from uremia.

Samuel D. Allen, Oak Harbor, Ohio; Homeopathic Hospital College, Cleveland, 1885; aged 65; a member of the Ohio State Medical Society; died, March 4, from cardiovascular renal disease.

Richard Llewellyn Stoddard, Rochester, N. Y.; Albany Medical College, 1895; aged 48; formerly a Fellow of the American Medical Association; died in the Lee Hospital, Rochester, April 29.

John A. Stevens, Clinton, N. C.; Jefferson Medical College, Philadelphia, 1883; aged 58; a member of the Medical Society of the State of North Carolina; died at his home, February 12, from nephritis.

Abram S. Wilson, Bristol, Pa.; Jefferson Medical College, 1881; aged 67; a member of the Medical Society of the State of Pennsylvania; died at his home, about April 22, from cerebral hemorrhage.

William P. McNally, Bangor, Me.; McGill University, faculty of medicine, Montreal, 1897; aged 52; a Fellow of the American Medical Association; died at his home, May 1, from pneumonia.

David Rosser, North Yakima, Wash.; Miami Medical College, Cincinnati, 1875; a member of the Washington State Medical Association; died at his home, April 23, aged 71, from paralysis.

Adelbert Dalton Atwood, Brooklyn; University of Buffalo, 1869; aged 68; formerly connected with the Brooklyn Board of Health Service; died at his home, April 28, from cardiac asthma.

James Addison Meriwether, Holcombs Rock, Va.; New York University, New York City, 1882; aged 65; a member of the Medical Society of Virginia; died at his home, April 30.

Lucius A. Walton, St. Louis; Washington University, Medical School, St. Louis, 1863; aged 77; a veteran of the Civil War; died at his home, April 28, from pneumonia.

Philip Pendleton May, Trevilians, Va.; Medical College of Virginia, Richmond, 1869; aged 73; a veteran of the Civil War; died at his home, April 29, from paralysis.

Mason Elias Henry, Pine Bluff, Ark.; Vanderbilt University, Medical Department, Nashville, 1912; aged 32; died at the home of his sister, Pine Bluff, La., April 26.

Henry Montgomery, Ypsilanti, Mich.; Michigan College of Medicine and Surgery, Detroit, 1904; aged 50; died at his home, March 2, from aortic insufficiency.

Uriah R. Shaeffer, Hummelstown, Pa., Jefferson Medical College, 1879; a member of the Medical Society of the State of Pennsylvania; died at his home, April 25.

James R. Hall, Carnesville, Ga.; Atlanta Ga., Medical College, 1892; aged 51; a member of the Medical Association of Georgia; died at his home, April 25.

Charles S. Phillips, Reading, Pa.; Medical-Chirurgical College of Philadelphia, 1895; aged 72; died at his home, April 29, from cerebral hemorrhage.

John W. Carmichael, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1886; aged 68; died at his home, May 2, from paralysis.

Thomas Alexander Brandon, Watford, Ont.; University of Toronto, Ont., faculty of medicine, 1911; aged 32; died at his home, April 27, from pneumonia.

Daniel Liberty Collom, Meadville, Pa.; Jefferson Medical College, 1876; aged 67; formerly a member of the city health board; died at his home, April 28.

Timothy Rose Grow, Lynn, Mass.; Hahnemann Medical College and Hospital, Chicago, 1877; aged 77; died at his home, April 22, from pneumonia.

William O. Bunnell, Wilkes-Barre, Pa.; Eclectic Medical Institute, Cincinnati, 1894; aged 50; died at his home, about April 20, from pneumonia.

George R. Baalith, Pittsburgh; Baltimore Medical College, 1906; aged 40; a Fellow of the American Medical Association; died at his home, March 4.

George Kent Colville, Pleasantville, Ohio; Ohio Medical University, Columbus, 1902; aged 51; died at the Grant Hospital, Columbus, April 23.

Elijah H. Gregg, Muncie, Ind.; American Eclectic Medical College, Cincinnati, 1887; aged 57; died at his home, April 26, from pneumonia.

Thomas Kennedy, Bermudian, Pa.; College of Physicians and Surgeons, Keokuk, 1874; aged 79; died at his home, April 29, from paralysis.

Lawrence Bryant Hathaway, Reinbeck, Iowa; Rush Medical College, Chicago, 1878; aged 64; died at his home, about March 17, from diabetes.

Elmore T. Applegate, Union City, Tenn.; Vanderbilt University, Nashville, 1883; died in Jonesboro, Tenn., April 19, from blood poisoning.

Arthur Joyal, Montreal, Que.; Laval University, Medical Department, 1883; aged 58; died at his home, February 6, from heart disease.

Andrew Allen Brown, Bangor, Me.; Bowdoin Medical School, Portland, Me., 1901; aged 42; died in Avondale, Ariz., about April 29.

John Paul Jackson, Norfolk, Va.; Southern Homeopathic Medical College and Hospital, Baltimore, 1895; died at his home, April 29.

Eli M. Downs, Columbus, Ohio; Starling Medical College, 1864; aged 80; died at his home, April 28, from cerebral hemorrhage.

Frederick Henry Parker, Auburn, N. Y.; New York University, Medical Department, 1881; aged 62; died at his home, recently.

David C. Fay, Ostrander, Ohio; Medical College of Ohio, University of Cincinnati, 1867; aged 74; died at his home, April 20.

John Wesley Shepard, Leoti, Kan.; Medical-Chirurgical College of Kansas City, 1904; died in a local hospital, April 25.

John A. Brown, Columbus, Miss. (license, Mississippi, years of practice); aged 80; died at the Columbus Hospital, April 25.

John Elmore Curtis, Waldron, Ind.; Kentucky School of Medicine, Louisville, 1888; died at a hospital in Indianapolis, April 28.

Simon H. Gump, Bedford, Pa.; University of Pennsylvania, Philadelphia, 1870; aged 71; died at his home, April 27.

Marriages

Major Giles Burneston Cook, M. R. C., U. S. Army, Richmond, Va., on duty at Camp McClellan, Anniston, Ala., to Miss Olive Smith, at Washington, D. C., April 30.

Lieut. Robert Douglas Spencer, M. R. C., U. S. Army, Philadelphia, to Miss Julia C. Butler of Hazelton, Pa., at Elizabeth, N. J., May 2.

Hunter Reece Mann of Mardela Springs, Md., to Miss Constance Agnes Vandergrift of Charleston, W. Va., in Baltimore, April 28.

Lieut. Walter Magruder Leonard, M. R. C., U. S. Army, to Miss Ruth A. Ralston, R.N., both of Fosterio, Ohio, April 17.

Lieut. John Edward Rueth, M. R. C., U. S. Army, Sun Prairie, Wis., to Miss Beatrice Miars of Milwaukee, May 7.

William Krauss of Memphis, Tenn., to Miss Margaret V. Curdy, formerly of Philadelphia, at Memphis, April 13.

Capt. Clifton Rodgers Dudley, M. R. C., U. S. Army, to Miss Margaret Gleason, both of St. Louis, May 1.

Brice Worthington Goldborough to Miss Margaret Craig Bayly, both of Cambridge, Md., May 8.

George Washington Guerinot to Miss Ursula M. O'Grady, both of Rochester, N. Y., April 10.

Charles Francis King of McKeesport, Pa., to Miss Corinn Smith of Philadelphia, May 8.

Max Tischler, to Miss Helen Micholosky, both of Wilkes-Barre, Pa., April 30.

Victoria McLaren Moore to Lewis Earle Barnes, both of Chicago, May 13.

Arley Glenn Everhart to Miss Emma J. Radtke, both of Chicago, May 11.

John W. Faust to Mrs. Zora Ray, both of Searcy, Ark., about April 23.

Paul H. Rupp to Miss Clarice Engh, both of Milwaukee, April 18.

Herman Horn, to Miss Lillian Kanes, both of New York, April 28.

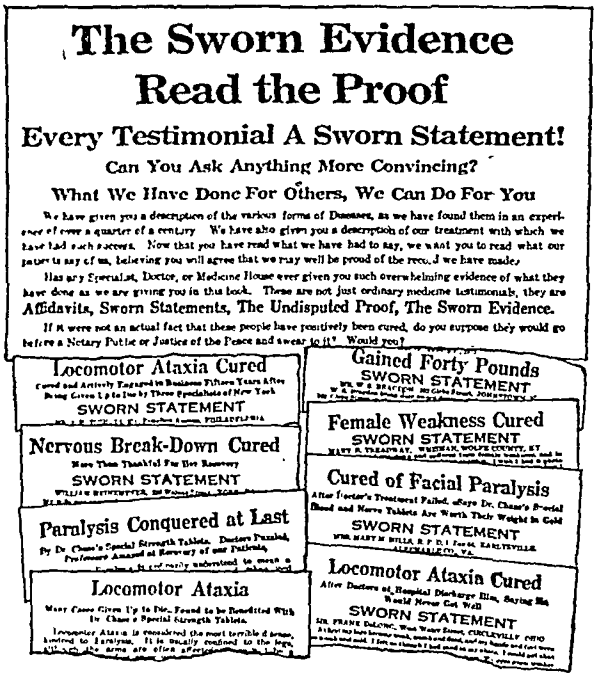
The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE DR. CHASE COMPANY

A Fraud Order Closes the Mails to a Nostrum Concern

For many years one Kossuth E. Hafer of Philadelphia has been defrauding the sick by selling alleged cures for paralysis, locomotor ataxia, kidney disease and numerous other conditions. Hafer conducted his business under the trade name "The Dr. Chase Company." He sold three remedies—pills—which, before the Food and Drugs Act made lying on the label irksome if not expensive, were known, respectively, as "Dr. Chase's Blood and Nerve Food," "Dr. Chase's Kidney Food" and "Dr. Chase's Liver Food." As none of these pills could by the widest stretch of imagination be called a "food," the names were changed, after the "Pure Food Law" went into effect, from "food" to "tablets." In those halcyon days for nostrum makers when everything "went" and the advertising pages of the majority of publications were open to any advertiser who could pay for space, the Chase concern advertised in some magazines of comparative respectability. During the past few years, however, the advertisements seem to have been largely confined to those cheap weeklies and monthlies whose advertising income is mainly derived from the less reputable products of the advertising world.



The Sworn Evidence
Read the Proof
Every Testimonial A Sworn Statement!
Can You Ask Anything More Convincing?
What We Have Done For Others, We Can Do For You

We have given you a description of the various forms of Diseases, as we have found them in an experience of over a quarter of a century. We have also given you a description of our treatment with which we have had such success. Now that you have read what we have had to say, we want you to read what our patients say of us, believing you will agree that we may well be proud of the record we have made.

Has any Specialist, Doctor, or Medicine House ever given you such overwhelming evidence of what they have done as we are giving you in this book. These are not just ordinary medicine testimonials, they are Affidavits, Sworn Statements, The Undisputed Proof, The Sworn Evidence.

If it were not an actual fact that these people have positively been cured, do you suppose they would go before a Notary Public or Justice of the Peace and swear to it? Would you?

Locomotor Ataxia is considered the most terrible disease, kindred to Paralysis. It is usually confined to the legs,

Locomotor Ataxia Cured
After Doctors at Hospital Discharge Him, Saying He Would Never Get Well
SWORN STATEMENT

Some pages and parts of pages (reduced) from one of the Hafer booklets. Note the claims that the pills would cure paralysis, locomotor ataxia, etc.

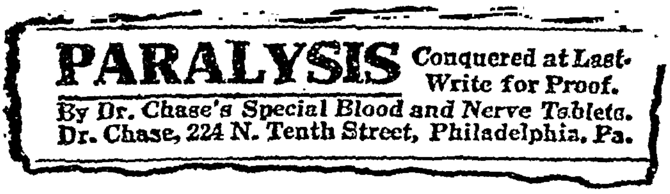
The federal authorities have investigated Hafer's business, and, very naturally, concluded that he has been conducting a scheme for obtaining money by means of false and fraudulent pretenses, representations and promises. Henceforth the mails are closed to the Dr. Chase Company.

In his case with the government Hafer had for his attorney H. B. Thompson, the counsel for the "patent medicine" interests, the "Proprietary Association." It seems fitting that the legal light of the Proprietary Association should have come to the defense of the Dr. Chase Company, which, by the way, seems to have been a member of that organization. The Journal has, before this, called attention to the fact that the membership of the Proprietary Association is secret and that, while it periodically protests that it and its members are *sans peur et sans reproche*, it is careful to prevent a general list of its membership becoming known.

Judge W. H. Lamar, the Solicitor of the Post Office Department, in his memorandum for the Postmaster-General recommending the issuance of a fraud-order, quotes quite fully from the claims made by Hafer in his advertising matter. In brief, it may be said that these claims were to the effect that the Dr. Chase Company had "spent years of time and thousands of dollars in perfecting the prescriptions" of the pills; that the pills had cured many cases of paralysis "of long standing, many of whom were pronounced incurable, given up to die and past the aid of human skill"; that "the Blood and Nerve Tablets" would "build up the blood and nerves faster than any other remedy"; that the "Special Kidney Tablets" would "give strength to the spine . . . stop all wasting of albumen through the urine, neutralize the uric acid, and relieve all rheumatic and sciatic pains"; that the "Liver Tablets" would "put the liver and stomach into such a perfect condition" that it would be impossible for those that took them to have sallow skin, foul breath, coated tongue, sour stomach, drowsiness after meals, constipation, etc.

In 1916 a Post Office Inspector interviewed Hafer and following this interview Hafer eliminated the word "paralysis" from the booklets he sent out (although he continued using it in his magazine advertisements) and substituted the phrase, "loss of power and strength." As Judge Lamar pointed out in his memorandum:

"A number of similar changes have been made with respect to other diseases; the paragraph relating to 'Gravel-Stone in the Bladder' has been omitted and promises of relief, while conveying the same sense, have been made less positive on their face. These changes clearly show the intent of Mr. Hafer to conduct this fraudulent business while evading, if possible, the consequences of his infraction of the law. In his attempt to do this he has not hesitated to change the language of the affidavits reprinted by him in such a manner as to substitute for the names and descriptions of diseases therein other names and descriptions which he thought would pass muster."



PARALYSIS Conquered at Last. Write for Proof.
By Dr. Chase's Special Blood and Nerve Tablets.
Dr. Chase, 224 N. Tenth Street, Philadelphia, Pa.

A typical advertisement. The one reproduced—slightly enlarged—appeared in the *Gentlewoman*, April, 1917. In 1916 Hafer had "hedged" on the use of the word "paralysis" in his advertising booklets—this following an interview with a post-office inspector. Violating the spirit of the law while making a pretense of keeping the letter is typical of the fraudulent "patent medicine" business.

The judge then states that the tablets sold by Hafer were composed of drugs well known to the medical profession and that the evidence demonstrated that these drugs, neither alone nor in combination, had the powers with which Hafer had endowed them. Continuing, the memorandum says:

"The holding forth of these tablets as curative, or even allevial, in all the conditions which may give rise to the symptoms enumerated, regardless of the condition of the patient or the cause of the trouble, is not only unjustified but flagrantly fraudulent. Some of the diseases from which these symptoms arise are incurable, some of them are only amenable to surgery, and many of them make no response whatever to drug treatment. According to the testimony adduced at the hearing in the great majority of these diseases these tablets are of no value whatever.

"Hafer, as might be inferred from the character of his representations, is entirely uneducated along medical lines.

"The business originated in his going to a chemical concern [The Wm. R. Warner Company, it is said.—En.] and having a tonic tablet made up in the business of selling which he intended to engage. He testified that at that time he had no intention of representing these tablets as of value in the various diseases which he included later in his advertising matter. This was done, according to him after persons to whom he had sold these tablets told him, that they had been cured of these various diseases. With no other basis for these claims, and little, if any, knowledge of the therapeutic value of those drugs, he proceeded to build up his claims without recourse to science or to experts along medical lines."

The memorandum further points out that if Hafer had been desirous of conducting his business honestly he would have sought knowledge regarding the value of these tablets from reputable sources of information, for he was put on notice several times as to the questionable character of his representations. He had, in fact, been cited before the Bureau of Chemistry for misbranding his stuff and modified his labels, which came under the purview of the federal Food and Drugs Act, but, as Judge Lamar points out, "at the same time he continued the same fraudulent representations to which his attention had been invited, in his advertising matter."

In 1917 Hafer was indicted for misbranding his preparations, pleaded guilty and was fined $250. "Under the circumstances," says the memorandum, "and in view of the evidence, I am constrained to hold that it was always his intention to go as far as he could in his claims for these tablets without regard to their actual value in the treatment of disease."

In view of all the findings, it was recommended that the Postmaster-General should issue a fraud order against the Dr. Chase Company. The mails were closed to the company, Jan. 17, 1918.

ADVERTISING PRINCIPLES—LAY AND MEDICAL

The Journal has received two letters, one from a physician who had written to the New York *Tribune* protesting against an advertisement of "Aspirin (Bayer)" that appeared in the rotogravure supplement of a Sunday edition and the other the New York *Tribune's* answer to the protest. The two letters make an editorial in themselves. Here is the letter of the physician—Dr. Edwin H. Shepard of Syracuse, N. Y.—which was addressed to the editor of The Journal:

> "When a great daily newspaper takes a stand for honest advertising it seems worthy that acknowledgement should be made. On April 14 the illustrated Sunday supplement of the *New York Tribune*, together with many of the other papers of the country, published a duplicate of the enclosed advertisement of 'Aspirin.' Your own instructive editorial on 'Acetylsalicylic Acid, or What's in a Name?' had appeared in the copy of The Journal of the day preceding.
>
> "Believing in the sincerity of the *Tribune* in its effort for honest advertising, I sent them a copy of your editorial together with the page of advertisement, also calling attention to the statements in the advertisement which seemed questionable. Among the questionable matters in the advertisement were the statements 'The one genuine Aspirin,' 'No other is genuine,' 'That which is genuine possesses qualities of excellence never found in imitations,' for your protection . . . every package and tablet is marked with the Bayer cross,' 'Your guarantee of purity,' and 'Refuse substitutes as they may prove ineffective and harmful.'
>
> "The *Tribune* was requested to investigate into the standing of the Bayer company and its product. A few days later the enclosed letter was received from the paper's Bureau of Investigations."

And here is the New York *Tribune's* answer, signed by R. R. Baer, assistant director of that paper's Bureau of Investigations:

> "We have your letter of April 14th, which was acknowledged on the 22nd, in re Aspirin. For your information: Our rotogravure supplement is printed a number of days in advance of the Sunday paper. When these copies which have already been printed are used, no further Aspirin copy will appear. This means a loss of some four pages."

How many of the numerous medical journals that are still carrying the "Aspirin (Bayer)" advertising would make such a financial sacrifice for mere principle?

Retain the Efficient Health Officer.—A tactful, energetic health officer can control the death rate in his locality provided he is given a few years to do it; but to expect great results in the time he ordinarily holds office is beyond power. —*Public Health* (Mich.).

Correspondence

BÁRÁNY CHAIR TESTS AND FLYING ABILITY

To the Editor:—In the article on "Bárány Chair Tests and Flying Ability" (The Journal, April 13, 1918, p. 1064), Parsons and Segar conclude with the statement that "the evidence, therefore, seems to point to an absence of correlation between equilibrium tests, as established in the Bárány chair, and actual flying ability."

While it is not clear just what impelled the writers to attempt "the correlation study of one hundred naval aviators," the article clearly implies to the medical reader unfamiliar with the principles underlying the tests of the internal ear that the Bárány test was intended to foretell the flying ability of the applicant tested. Just so far as this impression is conveyed by this article, the article is ill advised and untimely. It would naturally be as illogical and unwarranted to deduce that the aviator has no need of normal vision and eye muscle balance, on discovering that certain men who showed inaptitude at learning to fly possessed normal vision and eye muscle balance, as to make similar deduction concerning normal vestibular sense. The authors, in interpreting the examination of the vestibular apparatus as an attempt to determine the applicant's future proficiency under flying tutelage, have first formulated a hypothesis unheard of by the otologist, and then proceeded to prove it completely erroneous. Readers unfamiliar with the fundamental truths of the physiology of the internal ear and with the various methods of testing the vestibular apparatus are impelled to question the truth of teachings and tests in this comparatively new field of scientific medicine, and there is injected into their minds, by so raising doubts as to the soundness of these tests, a disquieting and disturbing element, quite unmerited by the scientific medical men who read to amplify their limited acquaintance with this apparently abstruse subject.

It is not impossible that this correlation study was intended as a psychologic research, in which case it would have been wise to make clear that such was the intention, and to publish it through the medium of a journal, the readers of which are psychologists and hence capable of recognizing psychologic research and placing proper construction on it.

Interest in the study of the vestibular function on the part of those as yet unfamiliar with it is particularly timely in this day of intensive development of great military air service. The general principles of labyrinthology are simple; the anatomic and physiologic details underlying them are somewhat complex; and a clear conception of the meanings of the tests is hardly to be expected to crystallize out of a few weeks or months of its study.

The writers introduce the subject of their article by saying, "Since the Bárány chair has been universally used by both the Army and the Navy in the selection of candidates for aviators," but they fail to state how long it is "since this chair has been used" in their service. This question cannot but be raised in the minds of those familiar with vestibular physiology by the second and third sentences in the article: "We knew, for instance, that trapeze performers and Russian dancers have very little, if any, nystagmus after whirling, and yet their proficiency in their performances depends on their sense of balance. We knew that men who have a so-called 'normal' nystagmus time before flying often lose all or a great part of it after numerous flights." These two statements have no foundation in truth. A scientific man who is familiar with this subject would need no actual tests to convince him of the unsoundness of such statements. However, tests have been made in the past of a large variety of whirling artists, in vaudeville, circus and dancing work, and in every case their responses to the standard stimulation of the vestibular apparatus were normal.

Epidemics of mumps among the flying schools have furnished opportunities of reexamining aviation cadets who had been tested previously, on the occasion of their admission into training, and had been found to have normal reactions to the vestibular stimulation. In some of these mumps cases both the cochlear and the vestibular functions were found to have been impaired seriously by the disease; in others, only the vestibular portion of the internal ear was found to have been affected. Special medical examinations have also furnished instances such as the following:

> An aviator, who had been examined and found to have normal responses to standard vestibular stimulation, and who had a record of months of successful flying on the west front, was finally noted by his flight commander to be flying progressively worse and worse, and experiencing greater and greater difficulties in making landings. At the instance of his flight commander he was sent to Major R. G. for special physical examination, and comparison with his former responses to vestibular stimulation showed a striking diminution in acuity of vestibular perception—from twenty-six seconds to seven seconds duration of nystagmus, and from three past pointings and proper falling to no past pointing and no falling. Further examination revealed syphilitic infection subsequent to his original vestibular tests.

It is not at all impossible that the cases coming to the knowledge of Parsons and Segar in which men having a so-called "normal" nystagmus time before flying lost all or a great part of it after numerous flights, were in reality similar to these just mentioned. It was unfortunate that accurate diagnosis of the cause of the loss in acuity of this special sense apparatus was not made and the details set forth in connection with allusion to the condition. Failing in this, the cases should not have been mentioned. This because, as the statement appears in the article, it is susceptible of only one interpretation, namely, that these men lost part or all of it after numerous flights solely because they had flown, which is plainly controverted by adequate available evidence showing the contrary to be true.

In saying, "it seemed to us, therefore, that for the most part the use of the chair has been taken more or less on faith after the following line of reasoning: A well defined sense of equilibrium is necessary for aviation. The Bárány chair determines the normality or abnormality of function of one's semicircular canals, which have to do with equilibrium. Therefore, by use of the chair, the sense of equilibrium of a candidate for aviation can be established. The question as to whether or not this line of reasoning is theoretically sound we are willing to leave to the otologists for argumentation," the authors make an assumption which is hardly in accord with the facts. One familiar with the work done on the labyrinth recognizes that it is merely a peripheral sense organ which, as Alexander C. Brown stated in 1876, "furnishes information of the change of aspect of the head in space." This normally has definite connections with the central nervous system by way of certain nerve paths and brain centers; the end-organs, nerve paths and brain centers constitute a special system or apparatus, which is commonly known as the vestibular apparatus. The semicircular canals may be determined to be functioning by standard tests, and yet there may exist a lesion preventing the normal operation of the vestibular apparatus.

Prior to the advent of neuro-otology, it would have been in the province of the neurologist alone to determine the location and character of such a lesion; the otologist, however, in dealing with the broad problems arising in the study of the vestibular apparatus, finds himself compelled to overstep the boundaries formerly confining his activities, and to avail himself of the information that otologic neurology places at his disposal.

The relative ability of an individual to utilize effectively the various special informations poured in on the central nervous system from all the special sense end-organs in no way could be conceived as falling within the province of otology or neuro-otology to determine.

It appears from the paper of Parsons and Segar that not all subjects examined have proved to be able to avail themselves of all the incoming special informations with equal facility; but it is not clear how it has been shown that the vestibular findings are specially involved. Until this has been pointed out, the relevance of their article is difficult to conceive.

Further allusion might be made to the incomplete data concerning those constituting the basis of this correlation study, particularly evidenced by the statement "unfortunately, all of these men had presumably passed a satisfactory Bárány examination." But it does not seem justifiable to go further in elaborating the defects so glaringly present both in premise and in development of this article.

To the Editor:—When the work of examining candidates for commissions as fliers in the Aviation Section of the Signal Corps began, the ocular requirements were placed at as high a level as possible: to be brief, a pair of perfect eyes was demanded, and that standard has never been lowered. The phrase "a pair of perfect eyes" might be transposed to "a perfect pair of eyes," for not only were the various functions of each eye to be considered with the greatest care, but also the relation of each eye to the other was most completely studied. So stringent were the demands made, especially on the muscular balance, that one of America's best known ophthalmologists expressed the opinion that if they were adhered to there would be no aviators, a rather amusing statement when placed in juxtaposition with some of the recent articles on this subject, the writers of which seem to be hazy as to whether even a demand for two eyes is made.

It was felt that perfect ocular mechanism was none too good when the demands made on it were considered—the start from the ground, the needs of observation, the estimation of distances, the quick recognition of approaching planes, whether friendly or hostile, and as important as any, the landing. During daylight hours, unless enveloped in cloud or fog, of course the eyes play also a very important part in the maintenance of equilibrium: this is realized and admitted by all concerned in the study of the mechanism of equilibrium, and on clear nights the visual impulse is useful in keeping right side up; but on cloudy nights, or when flying in cloud or fog, the aviator may as well be blindfolded for all help he receives from his eyes, and here a normal ear-balancing apparatus is most essential.

The standard of visual acuity was made $^{20}/_{20}$, uncorrected, in each eye, and it was most rigidly adhered to, no waivers being granted for deficiencies in this particular. Where a few seconds' difference in the time of two adversaries starting to maneuver, and where the advantage of position frequently mean the difference between life and death, it was felt that while quick perception and recognition of objects does not entirely lie in keenness of vision, this basic factor must be present in full degree. The near point must be consonant with the age of the candidate, and especial attention was given to this test with the view of eliciting all the information possible concerning the refraction of the eye. At first the refraction of each man was gone over under homatropin cycloplegia on the conclusion of all the other tests; but this was later abandoned, and the refraction was estimated by comparison of the near point, muscle balance and the ophthalmoscope. It was quite obvious that no myopes of over a quarter diopter could make the visual acuity demanded, and it was felt that hyperopia of over 2 diopters was not desirable, owing to the possibility of relaxation of the ciliary muscle under fatigue and the resulting blur of vision.

What limitations of muscular imbalance might be allowed with safety was a question that was most difficult to settle, and at least two alterations were made in the original determination. The maximum hyperphoria to be allowed was placed at 1 degree at the outset, and it was not changed, every one in authority agreeing that a wider deviation in this particular would possibly lead to actual diplopia on fatigue. The horizontal limits were not so easily defined: the final standard was not to allow more than 2 degrees of either exophoria or esophoria without doing prism duction tests, and if the relation between the abduction and adduction was maintained, to pass the man, provided, of course, the deviation was not too high; one over 4 degrees was seldom passed unless the man was especially desirable.

Normal color vision was considered a necessary asset, and was tested with Jenning's color chart; but slight variations in the recognition of extreme shades were considered as negligible, the feeling being that what was required was ability to determine the basic colors, and not all their tones. The visual field was examined only for form, the sensitivity of the retinal periphery for colors not being studied.

A careful examination of the pupil reaction to light, both direct and consensual, and to accommodation was required, and the rotation of the eyeball was studied for both inequality in action and nystagmus. Should the latter be developed within 45 degrees of central fixation, it was absolutely disqualifying. It was felt that some useful knowledge of the condition of the central nervous system might be obtained by these examinations, and great stress was laid on the examiner's being particular in making them. Ocular tension was tested by finger pressure unless there was some special reason for using a tonometer.

Since estimation of distance is one of the great requirements for a skilful pilot, the stereoscopic vision, was examined with great care. A card containing ten small silhouettes was used, and a correct reading of their sequence, by giving the number attached to each, was demanded. Of course, a normal stereoscopic vision will not enable an untrained person to estimate distance in the air with any accuracy, but it will be most helpful to him in attaining this accuracy and will be an essential factor in his making a safe landing.

After all other parts of the ocular examination were concluded, the pupils were dilated and an ophthalmoscopic examination was made.

Such an examination, it will be admitted, when properly made, would exclude all organic conditions that could interfere with the candidate's success as a pilot, and there remained only functional derangements. A most searching inquiry was made as to the candidate's having had attacks of migraine with scotomas or hemianopsia, diplopia or other ocular manifestations of disturbances in cerebral circulation; for not only would such an attack, should it occur in flight, be most disastrous, but such attacks usually indicate a none too stable nervous tone.

It will be admitted, it would seem, that the examination as above outlined tends to be rather searching in its scope and should satisfy even the most exacting critic. To be sure, certain things are not gone into which bring in what may be called the mental elements of vision; but these matters of judgment seem to be concerns rather for the psychologist than for the ophthalmologist.

H. Maxwell Langdon, M.D., Philadelphia.

◆

To the Editor:—I have watched with much interest the process of determining who are and who are not fit for the aviation service: what makes for and what against, a good aviator.

Unquestionably the aviator must be high in equilibration efficiency, and, no doubt, the semicircular canals have much to do with this, as do also the eyes.

It is my belief, however, that there is a certain something aside from both of these that is very important which we do not grasp at present—a certain sense of direction as well as equilibration, of which some individuals are more possessed than others, and which is susceptible to a high state of cultivation—the sense by which he who possesses it may return from a long ramble in strange forests or mountains and sit down and draw a very true map of the course he has taken; or at the end of his ramble can draw an accurate map of the way back, while another individual traveling with him will have no idea whatever of the direction in which return would be.

This sense of direction is highly developed in the pigeon. May it not be that from those wonderful carriers we can eventually discover the secret of that which makes a good aviator? Is there not possibly an association center controlling this matter of equilibration and direction—a *center for aviation*, so to speak?

Would it not be a good added test of the probable efficiency of an aviation candidate if he were put through some mechanical labyrinth or through by-ways of confusing directions, and then asked to point the way in a direct line to the spot from which he started? I believe that this would bring to light a surprising difference in the ability of different candidates to retain direction memory, or, in other words, to remember *which way is home*, a very important item to the flier in military service.

V. A. Chapman, M.D., Milwaukee.

A NATIONAL PUBLIC HEALTH DAY

To the Editor:—The celebration of Public Health Day in Philadelphia, May 1, 1918, concerning which a news item appeared in The Journal, May 4, excited considerable local interest in the subject of sanitation and the question of improving the national physique. It has been decided more recently by Dr. Krusen, director of public health and charities, to carry on follow-up work in the different sections of the city.

In view of the great importance of physical fitness of the civilian population, especially during the present critical period, I would suggest that a national public health day be celebrated as soon as practicable. In this connection, it is to be recollected that the percentage of rejections among our recruits (29 per cent.) is, sadly enough, too high, and a country-wide, systematic effort should be made to reduce it as rapidly as possible.

In this way a propaganda, having for its object an improvement of our national physical reserve, may be successfully inaugurated. The value of physical fitness will be accentuated through the observance of a national health day. We must not lose sight of the fact that the American race has been slowly and gradually deteriorating physically during the last century. It has been said that if the war is to be won it is to be won by health and certain constructive factors. It follows that among our home defense agencies, an improved national physique easily holds first place.

Moreover, it is vitally important that the civilian population should aim to increase its average man power for national service. There has already taken place a great diminution in the number of producers, because of the fact that many young men have enlisted in the military service and because production, especially farm production has been and must be further increased, not only to feed our own soldiers, sailors and the civilian population, but also to assist in the feeding of our allies abroad.

The recent appointment of physical reserve committees in every community under the auspices of the National Security League will doubtless accomplish good results, if their work is properly planned, since it will tend to upbuild the body, and to that extent improve the health of the general public. It is a matter of common observation by those who have considered the essential factors that enter into hygienic living that muscular activity has been greatly neglected by the average individual; hence a strong movement for the purpose of encouraging physical exercise in this country is both timely and important.

Additionally, however, a practical interest through an enlightened public sentiment, in municipal health rules and regulations, in germ diseases and how to escape them, in personal hygiene and the great economic value of physical fitness, is greatly to be desired.

I feel convinced that a national public health day, properly planned, would stimulate increased interests in, and attention to, the important work of improving the national physique, a matter of vital importance during the present crisis.

The celebration of such a day would mark the beginning of so-called follow-up work throughout the country during the ensuing year. This should consist, among other things, of an extension of the time devoted to personal hygiene, sanitation and preventive medicine in the upper grades of the public schools; also courses in these subjects in our colleges and universities, and a campaign of education in the interests of public health, in which our medical and civic bodies should actively and jointly engage. This follow-up work could be best conducted under the auspices of the American Medical Association, which touches the local profession everywhere. Indeed, the announcement by this leading organization of a national public health day at its forthcoming session would be likely to bear much fruit, particularly if President Wilson could be induced, which is quite probable, to issue a proclamation endorsing the movement.

Surely, the question of physical fitness at this time imposes an obligation on the organized medical profession.

James M. Anders, M.D., Philadelphia.

SERUM DIAGNOSIS OF SYPHILIS

To the Editor:—Referring to the article of Dr. Noguchi (The Journal, April 20, 1918, p. 1157) and his supplementary note (April 27, p. 1252) on the use of sodium acetate in preserving guinea-pig complement for the serum diagnosis of syphilis, I should like to add that while sodium acetate does work very well with many guinea-pig serums, it is not entirely satisfactory with some specimens, owing to a certain amount of precipitation that occurs occasionally. The sharp reactions and rapid hemolysis that tend to take place with complement preserved with the acetate has in my experience during the last six months indicated that in the weaker positive reactions they were more likely to become negative, thereby giving one a misleading result. This so far is the only criticism that I could make regarding the use of sodium acetate for the purpose. I might say that with the ice-box method of preliminary incubation as done by the New York Board of Health, the use of complement preserved by the acetate has proved highly satisfactory, while a check with the same specimens, using the same reagents, has given an end-result that shows either a complete or partial hemolysis except in the strong positive cases.

Referring to the use of the native complement in human serums in making the Wassermann test, I desire to say that there are a certain number of serums that contain sufficient native complement for the test, yet at the same time these serums are more or less anticomplementary in the active state, which property is somewhat increased during the first hour's incubation, tending to produce a false positive result in otherwise negative serums. This particular variety of serum is found sometimes in patients that are jaundiced, and even inactivation does not always destroy the anticomplementary substance. Bile in the blood is likely to cause misleading results, and has already been mentioned in the work of several serologists.

I should like to know if the best procedure in testing those serums that are slightly anticomplementary would not be a careful titration in the active state in addition to inactivation and further tests with increasing amounts of guinea-pig complement. It should be emphasized that many serums are even too anticomplementary after inactivation for dependable results, and the only thing to do is to draw another sample of blood and repeat the test. Where bile is a disturbing element, a calomel purge may produce the desired result. Other conditions may be cleared up by change of diet, etc., as the well known milky serums usually found after a hearty meal. I often encounter the so-called "milky" serums under other conditions, and they are all practically more or less anticomplementary after inactivation.

There is no doubt that the ideal Wassermann test would be a careful titration, using the native complement present, provided the antigens are acetone-insoluble preparations and a careful check is made on each serum for anticomplementary properties. The much heralded Hecht-Weinberg and its various modifications depends for its reputation on the native complement, natural antisheep amboceptor, etc. With this new method as outlined by Dr. Noguchi one can easily get the index by using enough tubes, varying the amounts, etc.

There are many laboratory workers who condemn every new method that appears before a thorough trial, thereby causing the general practitioner to adhere to this or that particular test or modification, because the advertisement says it is the best, without fully understanding the principles involved.

It is, I think, generally conceded by most serologists that both the cholesterinized and the alcoholic (preferably the acetone-soluble) antigens should be used with each specimen tested. This is not being followed by some, and only emphasizes one more reason why we should have a standard technic, at least a standard antigen or a prescribed method for making one; there is as much indication for a standard antigen as there is for a standard unit for diphtheria and tetanus antitoxin, and I hope to see the U. S. Public Health Service adopt a standard antigen if not a standard method.

S. S. Hindman, M.D., Toledo, Ohio.

◆

To the Editor:—Dr. Hideyo Noguchi, in his article on serum diagnosis of syphilis under war conditions (The Journal, April 20, 1918, p. 1157), mentions that in strongly positive serums complement is fixed wholly in twenty minutes at 21 C., but that on account of weaker reactions the time for fixation should be prolonged to two hours. In recent experiments I have found that complement is completely fixed practically at once at room temperature. The results of a number of special tests indicate that in routine tests it probably is quite sufficient to allow the serum-complement-antigen mixture to stand for ten minutes before adding corpuscles and amboceptor. This seems to be time enough even with weakly positive serums and spinal fluids. As I am unable to make comparative tests on a large scale, I hope that the possibility of shortening the time of the Wassermann reaction in the way indicated may be studied further by others more favorably situated for the purpose.

J. M. Retinger, Chicago.

THE PHARMACIST IN THE ARMY MEDICAL DEPARTMENT

To the Editor:—There seems to be a well defined attitude toward pharmacists in the Army—that of almost completely ignoring their professional distinction, along with an amazing indifference as to their proper place and utilization. Needless to say, such a policy results not only lamentably as regards the pharmacist's status in the Army, but his professional value is lost to the Medical Department.

It is also quite apparent that since modern war machines are essentially and thoroughly businesslike in structure and character, modern methods must be employed to achieve success. It is therefore logical and imperative that every branch and wing of that complex machine be conducted on the modern principle of specialization. The trained man, the specialist, was never more desirable, never more absolutely indispensable. Such a principle is the very backbone of all modern institutions, and invariably spells success. Division of labor and centralized effort are built, supported and owe their existence to the specialist—the trained man.

The pharmacist is a specialist, trained in a part of medical science that cannot be ignored without affecting the efficiency of the Medical Department as a whole. A pharmacist's business ability to buy and distribute should be taken advantage of in medical supply depots. His experience would help to correct mistakes in buying and avoid improper packing for distribution of such supplies. This part cannot be emphasized too strongly, since it would effect an enormous economy hardly ever appreciated by nonprofessionals. Likewise a pharmacist would be invaluable at large base hospitals, and his recognition becomes imperative when the dangers of the improper compounding of prescriptions by nontrained men are fully realized.

Aside from sentimental considerations for the pharmacist as an underpaid, neglected professional, his recognition is dictated by common sense and cannot fail to justify itself from a business and economical standpoint. Never would such a step be more timely, never was it more obvious and desirable. Indicting criticism of the present system of the neglected pharmaceutical branch of the Medical Department could be easily brought to light. The method of packing for distribution could be pointed at as wasteful, which a professional eye could readily detect and condemn. Immense savings could be gained even in the small Army dispensaries were the business end of medical supplies placed in the hands of the logical man—the pharmacist. As for prescriptions, their importance and the skill required for their preparation cannot be overlooked. The idea that a bright private could be taught to perform the few simple operations is not only fallacious but also fraught with dangers.

Perhaps the following incident will serve to illustrate the folly of just such a belief: At an examination for promotion to the grade of sergeant, the aspirant was asked what a "C. C. pill" is. "Any pill containing one cubic centimeter." was his immediate reply. Another applicant was asked how to administer a Seidlitz powder. "Place the powder on the patient's tongue and wash it down with water," was his answer.

Pharmacy is a science—as exacting and important as the science of surgery—and a pharmacist's place should be second only to that of the surgeon. Are civilians more entitled to protection against mistakes of unskilled hands than soldiers?

Albert White, Post Dispensary, Corozal, C. Z.

MODIFIED LAVATORY CHAMBER

To the Editor:—In The Journal, May 18, Dr. Zan D. Klopper of Chicago has an article entitled "The Practicability of the Modification of the Lavatory Chamber." This is not a new idea, as the late Dr. B. Howard Rand, professor of chemistry in Jefferson Medical College, in 1876, drew a diagram similar to Figure 2 in Dr. Klopper's article, on the blackboard before his class. His idea was superior to Dr. Klopper's, as he not only embraced all of the doctor's but he had a cover to the seat with a spring attachment to compel the individual to keep his body bent forward. The idea was not only to aid defecation but to prevent the occurrence of a hernia.

J. B. Potsdamer, M.D., Philadelphia.

[Note.—Dr. Klopper claimed no originality for the theory. The physiologic basis for the position which he described has been understood for many years. He did, however, work the matter out in some detail and presented drawings to enable those interested to design a proper apparatus.—Ed.]

ARSPHENAMIN (SALVARSAN) REACTIONS

To the Editor:—Many have gained the impression that arsphenamin is a severely toxic spirocheticide. I believe that none of the American preparations are as toxic as was the German-made salvarsan. Many physicians have used the American products in our laboratories, and have found the reactions fewer and lighter than were formerly noticed with the German-made salvarsan. These deductions are made from several thousand treatments with the German salvarsan and the American-made salvarsan and arsenobenzol. An unfortunate feature is that many physicians have substituted other forms of antisyphilitic treatment, with the result that the patients do not have such an efficient destruction of spirochetes as they did with the use of salvarsan. When a death or severe reaction follows the use of one of these drugs, it is reported both in the public and in the medical press, but very little is said of the thousands of favorable results.

Occasionally a reaction may occur from other causes than faulty technic. All patients who are to receive an intravenous arsphenamin treatment should have a laxative the night before, should not have any breakfast, and should not eat a full meal the same day that the arsphenamin is administered. Some patients that have taken several intravenous arsphenamin injections without any reactions have had reactions of variable degree following treatment soon after a full meal. Reactions have occurred in a large percentage of patients who have eaten a large meal within six or eight hours after treatment. These reactions come on slowly with headache, nausea, vomiting, diarrhea and a temperature of 102. The symptoms may last two days.

In preparing the solutions we recommend the use of triple distilled water, redistilled through glass, mixing the salvarsan brand of arsphenamin in about 50 c.c. of cold water, never over 100 F., and preferably under that. The solution is neutralized with sodium hydroxid and then filtered through a sterile cotton filter into 100 c.c. of cold redistilled water.

With the arsenobenzol brand of arsphenamin it is necessary to dissolve in hot water; otherwise the technic is the same. Hot water should never be used in preparing the salvarsan brand. With both preparations the intravenous injection should be made within a few minutes after the material is prepared.

H. S. Warren, M.D., Chicago.

THREE DROP METHOD OF DETERMINING HEMOGLOBIN BY THE TALLQVIST SCALE

To the Editor: In working with the Tallqvist hemoglobin scale, I find that by taking three drops of blood about 2 cm. apart, each drop coming under an opening in the scale, one can determine the results of the hemoglobin test much better than by the one drop system, as it affords three scales to read from at once.

R. J. Weidmann,
Takoma Park, D. C.
Corporal, Medical Department, U. S. Army.

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BREATH HOLDING IN CHILDHOOD

To the Editor:—Please give cause and treatment for child holding its breath to the point of cyanosis and convulsions, seen most often when crying from anger.

W. T. Potter, M.D., Aurora, N. C.

Answer.—This condition of breath holding, also called inspiratory apnea, is not infrequently observed in early childhood. At first one would be led to think that the condition is a manifestation of spasmophilia or tetany with the associated laryngeal spasm and generalized convulsive seizures. On further investigation, however, this is not confirmed. Breathing is arrested or remains stationary in the midst of the crying attack, but no inspiratory spasm occurs. The child attempts to cry, but the inspiratory muscles remain in a tonic state. He throws himself about, becomes extremely pale and finally cyanotic, the body becomes rigid, the eyes turn or become set, and he loses consciousness momentarily. The attack usually lasts only a few seconds, though it may continue several minutes. In the more severe cases, general convulsions may occur. When the spasm relaxes the child cries, though he resumes normal breathing, and soon acts as though nothing had happened, or falls asleep.

This condition also suggests a possibility of epilepsy, or other organic changes in the central nervous system. It is true that the differentiation of attacks of inspiratory apnea or breath holding from true epilepsy may present great difficulties. Nevertheless, it should be pointed out that the breath-holding attacks follow immediately after severe crying or excitement, while epileptic attacks occur suddenly while the child is at quiet play or even during sleep. Biting the tongue is characteristic of epileptic attacks. Involuntary evacuation of the bladder or bowels may occur in either attack. Prolonged sleep usually follows an epileptic seizure and is characteristic, though in some cases of breath holding, the prostration may be so great that a prolonged sleep, lasting several hours, ensues after the attack.

These attacks of breath holding occur most commonly in the second and third years of life, and disappear about the fifth year, whereas the genuine spasmophilia occurs during the first year or two of life. These occur in neuropathic children and are brought on by fear, anger, fright or some other psychic trauma. The children are irritable and ill tempered. Parents fear the recurrence of the attacks and consequently humor them in every possible way. They permit no one to cross the child, no whim remains ungratified, and the little patient is not helped to offer resistance to the recurring attacks. Patients practically always recover after some time, although the attacks may be severe and protracted. It has been pointed out that children with this disorder who fall ill with an acute infectious disease, or who may happen to need some surgical treatment, may become so severely frightened that a protracted breath-holding attack with general convulsions may be so severe as to terminate fatally.

The treatment should be directed toward the general management of a nervous child. He should be warned not to repeat the attacks. Every form of mental overstimulation should be avoided. Frequently patients improve most rapidly if they are removed from the excitement and tension of home surroundings. A short stay at the hospital away from parents and friends is often advisable. Bromids are advised in addition to psychotherapy. During the attack the child may be sprinkled with cold water or he may be immersed in a cold bath.

NUMBER OF MEDICAL RESERVE OFFICERS NEEDED—SALARIES, EXPENSES AND ALLOWANCES

To the Editor:—Please answer these questions regarding the Medical Reserve Corps of the Army and Navy:

1. How many medical men will be needed after the present enlistment of 5,000?
2. Are there openings in the Navy? How many are needed there, and what salary is paid?
3. What is the cost of a complete officer's equipment in each service?
4. What provision does the government make for dependents of officers in the way of money provision outside of the regular salary?
5. What are the salaries of officers in the Army?
6. I have been told that an officer does not receive pay until in active service, which means to me that after receiving a commission the candidate is sent to one of several places for instruction, paying his own railroad fare and paying his own expenses, his salary starting when he begins duty at one of the several cantonments. Is this correct?

Frederick A. Baker, M.D., Rudyard, Mich.

Answer.—1. The call of the Surgeon-General is for 5,000 additional reserve officers before Jan. 1, 1919, and at least 2.500 additional each year long as the war continues.

2. The Navy will probably require 1,000 additional reserve officers during the next year. The salaries paid are: rank of lieutenant, junior grade, $2,000 per year and $432 allowance for quarters when not furnished by the government; rank of lieutenant, senior grade, $2,400 and allowance for quarters, $576; rank of lieutenant-commander, $3,000 and allowance for quarters, $720. There are also liberal allowances for heat and light, the amount varying according to rank, etc.

3. For the cost of the equipment of a medical officer in the Army, see The Journal, May 18, 1918, p. 1469. When naval officers first report for active service for training they are accredited with a clothing allowance of $50, except in the Volunteer Naval Reserve not on active duty. When on active duty, members of the Volunteer Naval Reserve receive the service pay of their grade and service.

4. The only money provision made by the government for officers with dependents, outside the regular salary, is the allowance for quarters which is as follows: first lieutenant, $36 per month; captain, $48 per month; and major, $60 per month.

5. The salaries of medical officers in the Army are: first lieutenant, $2,000 a year and allowance for quarters, fuel and light; captain, $2,400 a year and allowance for quarters, fuel and light; major, $3,000 a year and allowance for quarters, fuel and light. The allowance for quarters is granted only to those with dependents; the allowance for fuel and light varies according to tables published by the Comptroller's Department.

6. Medical reserve officers of the Army when ordered to active duty to receive instruction, either in training camps or in other courses of instruction, receive pay from the time they first report for duty or for instruction. They also receive traveling expenses to their various stations.

THE DUNFERMLINE SCALE

To the Editor:—Please tell me what the Dunfermline scale is or where I can find information about it. It is mentioned as used by the Bureau of Child Hygiene of the New York City Health Department in a survey of schoolchildren of Manhattan (The Journal, April 27, 1918, p. 1257).

E. C. G.

Answer.—The Dunfermline scale is a scheme for classifying children according to their degree of nutrition. It was devised at the College of Hygiene and Physical Training and School Clinics in Dunfermline, Scotland, founded by the Carnegie United Kingdom Trust. Children are placed in four nutrition grades: (1) superior condition; (2) passable condition; (3) requiring supervision, and (4) requiring medical treatment. In the 2,535 children examined in New York, the first two grades included each approximately one third of the total number, and the remaining third was divided between the other two.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 9. Chairman, Dr. S. W. Welch, State Capital, Montgomery.

California: San Francisco, June 25. Sec., Dr. C. B. Pinkham, State Capitol, Sacramento.

Colorado: Denver, July 2. Sec., Dr. D. A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 9-10. Sec. Regular Bd., Dr. Chas. A. Tuttle, 196 York St., New Haven; Sec. Eclectic Bd., Dr. J. E. Hair, 728 State St., Bridgeport; Sec. Homeo. Bd., Dr. E. C. M. Hall, 82 Grand Ave., New Haven.

Vermont: Burlington, June 10-12. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 18-21. Sec., Dr. J. W. Preston, Roanoke.

Washington: Tacoma, July 2. Sec., Dr. C. N. Suttner, 415 Old Nat'l Bldg., Spokane.

West Virginia: Wheeling, July 9. Health Com., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Wisconsin: Milwaukee, June 25-27. Sec., Dr. J. M. Dodd, Ashland.

Addenda to State Board Statistics

Table D on pages 1084 and 1085 of The Journal of April 13, 1918, was based on signed reports from the various state licensing boards. New York and New Jersey have since reported that the University of Virginia Department of Medicine, the University of Illinois College of Medicine, and the Hahnemann Medical College of Chicago have been admitted to their registered lists. The secretary of the Kansas State Board of Medical Examiners also had reported that only Class A medical colleges were granted recognition. In a later communication he states that Class B colleges will be recognized until 1922. The medical schools now rated in Class B for which recognition in Kansas has been extended until 1922 are: University of Arkansas Medical Department, Little Rock; College of Physicians and Surgeons, Los Angeles; College of Medical Evangelists, Loma Linda; Loyola University School of Medicine, Chicago; Hahnemann Medical College and Hospital, Chicago; New York Homeopathic Medical College and Flower Hospital, New York; Leonard Medical School, Raleigh; Eclectic Medical College, Cincinnati; Ohio State University College of Homeopathic Medicine, Columbus; Temple University Medical Department, Philadelphia; Meharry Medical College, Nashville, and Fort Worth School of Medicine, Fort Worth, Texas.

Connecticut March Examination

Dr. Charles A. Tuttle, secretary of the Connecticut Medical Examining Board, reports the practical and written examination held at New Haven, March 12-13, 1918. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 17 candidates examined, 10 passed and 7 failed. Two candidates were granted reregistration licenses. The following colleges were represnted:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1917)	83.1
University of Maryland	(1907)	76.6
Tufts College Medical School	(1915) 75.6; (1917)	83
Columbia University	(1918)	82.8
Fordham University	(1918)	81.8
University and Bellevue Hospital Medical College	(1918)	88.8
University of Pennsylvania	(1917)	77.8
University of Vermont	(1917, 2)	76.5
FAILED		
University of Maryland	(1916) 74.1; (1917)	72
College of Physicians and Surgeons, Boston	(1908)	54.5
University of North Carolina	(1910)	59.3
University of Vermont	(1914)	60.9
Medical College of Virginia	(1917)	63.3
National University, Athens	(1911)	58.3

District of Columbia April Examination

Dr. Edgar P. Copeland, secretary of the Board of Medical Supervisors of the District of Columbia, reports the oral and written examination held at Washington, April 9-11, 1918. The examination covered 16 subjects and included 80 questions. An average of 75 per cent. was required to pass. Ten candidates were examined, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
George Washington University	(1917)	89.2
Howard University (1910) 82.6; (1917) 90.6;	(1918)	77.8, 80, 81
Baltimore Medical College	(1905)	80.1
Harvard University	(1904) 80.4; (1908)	84.7
University of Vermont	(1912)	75.4

Book Notices

Radiography and Radio-Therapeutics. By Robert Knox, M.D., M.R.C.S., L.R.C.P., Consulting Radiologist, Great Northern Central Hospital, London. Part I, Radiography. Cloth. Price, $9. Pp. 403, with 115 illustrations. New York: The Macmillan Company, 1917.

This is one of the best books covering the subject of general roentgen diagnosis issued within recent years. It is especially adapted for use by the general practitioner or the student of roentgenology, although it contains much of interest and information of value to the specialist in this line. It has been thoroughly revised to cover the field to the date of issue, describing modern equipment and the technic employed. The chapter on the localization of foreign bodies by methods used in the present war is of special interest at this time. Numerous plates of gas gangrene cases are shown. The work is well and profusely illustrated, and covers the subject with a thoroughness that leaves little to be desired in a volume with so broad a scope.

Meat and Luxury.—So far as is known, taking meat even in large excess is not harmful, but it represents luxury and waste.—Lusk, Food in War Time.

Medicolegal

Color Blindness as a Loss of Sight

(Routt v. Brotherhood of Railroad Trainmen (Neb.), 165 N. W. R. 141)

The Supreme Court of Nebraska affirms a judgment for the plaintiff for $1,740, the full face of a benefit certificate held by him in the defendant association, and interest, on account of his having become afflicted with color blindness and for that reason having been discharged from the service of a railroad company that had employed him as a railroad trainman. A rule of the association provided that any beneficiary member in good standing who should suffer the complete and permanent loss of sight of both eyes should be considered totally and permanently disabled and should thereby be entitled to receive the full amount of his beneficiary certificate. The plaintiff contended that as a railroad trainman he had become totally blind, and that within the terms of the policy held by him in the defendant association he had suffered the complete and permanent loss of the sight of both eyes, which the defendant denied.

The condition, the supreme court says, was not made that the eyes of the insured should be taken out of their sockets and away from his physical body, but only that he should "suffer the complete and permanent loss of sight of both eyes." It did not say that he should become blind in both eyes so as to become unable to see objects of any kind, but that he should lose "the sight of both eyes." This he did when he became color blind. He lost his sight in both eyes. It affected both eyes alike. Besides, the color blindness was "complete and permanent." He could not see, and that applied to both eyes, and he was discharged because the defect in his vision made him unfit for railroad service. The thing for which he sought indemnity, loss of his vision, came to him. If his insurance did not indemnify him, it served no good purpose. Besides it was ambiguous and misleading, and should be construed as the defendant knew the plaintiff would understand it.

Where the peculiar malady known as color blindness so impairs the sight that the member of a fraternal insurance association of railroad trainmen who is insured therein is unable longer to continue in the train service, and is discharged therefrom on account of such defect in his vision, it will be held that he is entitled to the benefits provided by the certificate, the constitution, and by-laws and rules of the society. In such case, while the sight of the insured may not be entirely destroyed for some purposes, it will be deemed destroyed and lost as to the particular vocation of a railroad trainman, and he will be held entitled to recover on the benefit certificate which he holds. Three members of the court dissent.

Employment of Jail Physician and Remedy of Latter

(Sawyer v. Commissioners of Androscoggin County (Me.), 102 Atl. R. 226)

The Supreme Judicial Court of Maine directs a peremptory writ of mandamus to be issued to compel the county commissioners to fix the pay of the petitioner for services as jail physician. The court considers at some length the question of who, if either, the county commissioners or the sheriff, has the legal right to employ a physician to render medical attendance to sick prisoners confined in jail. The court says that there is no statute in Maine conferring express authority either on the sheriff or on the county commissioners to employ a "physician authorized to attend the sick," as expressed in Chapter 85, Section 47, of the Revised Statutes of 1916, or "the physician appointed to attend said prisoner," as said in Chapter 127, Section 26. Yet these expressions and the necessity of such action necessarily imply the duty and power of some authority, having the control and custody of prisoners, who are helpless in their own right, to employ a physican to administer to the welfare of the prisoners in the county jail at the expense of the county. This authority once implied from the statutes is as positive as if expressed in the statutes.

The situation presents a county containing a jail erected and supported for the confinement and detention of the prisoners that may be committed to it. These prisoners are in the custody of the law and helpless. They can neither confer nor communicate with the outside public except through the medium of some official agency. Their health, as an infliction on themselves, or as a menace to the other prisoners, as in the case of an infectious or loathsome disease, depends on official attention These are not theoretical, but actual, conditions. These circumstances demonstrate the necessity of lodging authority in some agency that can act quickly and efficiently in the employment of medical aid. In view of the official functions of the sheriff, as jailer, and the county commissioners, officers of the county, which agency is the better adapted to meet the requirements of this situation? The conclusion reached by the court is that an interpretation of the statute, by express language, *not only gives, but imposes on*, the sheriff or his deputy, as jailer, the sole responsibility for the care, custody and safeguarding of the prisoners, and by necessary implication authorizes him alone, when necessary, to employ a physician to administer to the prisoners.

It having been determined that the sheriff had the implied power to employ a physician to treat the prisoners, was the physician entitled to the remedy of mandamus? This question could be settled by the process of elimination. Section 27 of Chapter 85 of the Revised Statutes provides that for all subordinate assistants and employees of the jailer the county commissioners shall fix their pay. They therefore cannot bring suit against the county until the pay is fixed: 1. The commissioners, while they had refused to pay the bill presented by the physician in this case, had not fixed his pay. Hence he could not bring an action of assumpsit on an implied contract or quantum meruit (for the reasonable value of his services). 2. He was not a public officer. He was an employee. His employment was conceded. The legality of his employment only was in question. Hence quo warranto did not lie. 3. The county commissioners had not acted, according to the statute, on his bill. They had rejected it, not "fixed his pay" as something or nothing. Hence certiorari would not lie. It quite clearly appeared that no remedy would lie except on a petition for mandamus. The petitioner must show that he was legally employed and had a claim against the county on which it was the duty of the county commissioners to fix the amount to be paid. The legality of his bill depended on the legality of his employment.

Not Liable for Injury to Patient Escaping from Pesthouse

(O'Brien v. Stromme et al. (Mont.), 169 Pac. R. 36)

The Supreme Court of Montana says that the complaint alleged that the plaintiff, being afflicted with smallpox, was taken to the pesthouse maintained at or near Butte for the accommodation of such cases by the Silver Bow County Board of Health; that while in delirium from the disease and because of the board's failure to provide sufficient guards, he escaped on a cold winter's night and so froze his feet that amputation of several toes became necessary, for which he claimed damages. He was nonsuited at the trial, and sought by appeal to present the question of whether the members of the board were liable. The judgment of nonsuit is affirmed.

Conceding that if, in arranging to care for matters of this kind, the board acts judicially or quasi (as it were) judicially, no liability for mere mistakes would exist, the plaintiff insisted that the defendants were liable on the theory that the duties of the board in the premises were ministerial, and for negligent nonfeasance or misfeasance the members must answer to whosoever is injured thereby. Whether this was correct the court might not decide here because the record did not show negligence or any injury due to negligence. It was true that practically all the evidence offered by the plaintiff for that purpose was excluded on objection—why, this court does not entirely understand; but since no question was made of the correctness of these rulings, this court could not import into the record what the plaintiff did not prove. No more than any one else can public officers be held to respond for injuries until it is shown that their fault is the proximate cause of such injuries.

2 *Hypertonic Infant; Curative Action of Atropin on Certain of Its Manifestations. S. V. Haas, New York.—p. 323.
3 Effect of Hunger on Nervous Irritability. J. R. Gerstley and R. G. Hoskins, Chicago.—p. 336.
4 *Treatment of Enuresis without Drugs; Report of Thirty-Four Consecutive Recoveries. W. R. P. Emerson, Boston.—p. 339.
5 Xanthochromia of Spinal Fluid with Complete Coagulation in Tuberculous Meningitis. D. B. Leitch, New York.—p. 348.
6 Pylorospasm and Congenital Pyloric Stenosis. J. Foote, Washington, D. C.—p. 351.
7 Congenital Intestinal Obstruction; Report of Case. A. V. St. George, New York.—p. 354.

1. **Value of Tuberculin Tests.**—Each child was given a von Pirquet test which was observed after twenty-four, and again after forty-eight hours. If positive, this was regarded as evidence of tuberculous infection. If negative after forty-eight hours, a second von Pirquet test was performed. After forty-eight hours a third test was made. If this proved negative, an intradermic injection of 0.1 c.c. of 1:1,000 old Koch tuberculin (that is, 0.1 mg.) in saline solution was given. If after forty-eight hours this was negative, 0.1 c.c. of a 1:100 solution (that is, 1 mg.) was injected and repeated after forty-eight hours if negative. If after these six tests the case still failed to react, it was considered definitely negative. In all, 1,165 tests were made on 206 children. In all, fifty-two children showed a positive reaction to some of the tests, a percentage of 25.2. If but a single von Pirquet test had been employed the incorrect conclusion would have been drawn that only 3.3 per cent. of the inmates had been infected with the tubercle bacillus. If two von Pirquet tests had been used the percentage would have been doubled (6.8), and so on, until by the use of the intradermic tests the true percentage of infected cases was found to be 25.2.

2. **Atropin for Hypertonic Infant.**—The hypertonic infant shows a tendency to rigidity, overaction of involuntary muscles and soon after birth develops signs of physical and psychic irritation, presenting the syndrome (physical) of vomiting, often visible peristalsis, constipation and imperfect nutrition; (psychic) or general irritability, insomnia and crying. In Haas' opinion the etiologic factor of this state would appear to be a hyperexcitability of the autonomic nervous system. Although apparently a feeding problem, changes in method and character of feeding does not correct the condition. Atropin in doses of 1 drop or more of a 1:1,000 solution with each feeding usually relieves the condition at once and apparently increases the infant's tolerance for milk. Atropin in these cases may be used in large doses without danger. Haas suggests that investigation along these lines may reveal the etiology of hypertrophic pyloric stenosis.

4. **Drugless Treatment of Enuresis.**—The children included in Emerson's series of thirty-four cases all recovered without the use of any drugs whatsoever. The treatment is directed toward teaching the child the "dry habit" and, on the other hand, of interrupting and eliminating the "wet habit." This treatment consists of four methods, all or one of which may be used in a given case to establish the "dry habit." The "dry habit" once inaugurated must then be continued by careful oversight. 1. Mental suggestion. 2. Establishing the "dry habit" by teaching the reflex to act at regular intervals, and always before the time the "wet habit" occurs. 3. Local irritation by irritating the vesicular sphincter and the posterior urethra by means of a bougie-a-boule, so that sensory impulses passing to the brain will become intensified sufficiently to attract the patient's attention, until the habit of control is attained. 4. Cerebrospinal irritation is produced by the injection into the spinal canal of physiologic sodium chlorid solution, producing such stimulation as to arouse the whole mechanism into consciousness when habit holds it under control. These methods singly or combined, have been sufficient to relieve the thirty-four children in this series.

American Journal of Physiology, Baltimore

April, 1918, **46**, No. 1

10 *Id. Regulation of Urea Excretion by Unknown Factors. T. Addis, G. D. Barnett and A. E. Shevky, San Francisco.—p. 22.
11 Salivary Factor in Relation to Dental Caries. P. R. Howe and M. R. Keniston, Boston.—p. 28.
12 *Influence of Music on Electrocardiograms and Blood Pressure. I. H. Hyde and W. Scalapino, Lawrence, Kan.—p. 35.

8. **Regulation of Urea Excretion by Concentration of Urea in Blood and in Urine.**—According to the authors neither the concentration of urea in the urine nor the volume of urine are factors which appreciably influence the rate of excretion of urea.

10. **Regulation of Urea Excretion by Unknown Factors.**—There was a progressive increase in the rate of urea excretion in consecutive observations on rabbits subjected to catheterization and bleeding, so that at the last the rate is nearly twice as great as at the commencement of the experiment and exceeds the rate yielded by the rabbit under the same conditions except for the absence of handling. This increase in the activity of the kidney occurs in spite of the absence of any change in blood urea concentration.

12. **Influence of Music on Cardiovascular System.**—The object of the experiment made by Hyde and Scalapino was to ascertain the effect of different kinds of music on the heart and blood pressure in individuals who are known to have musical talent and are fond of music; also in persons who are indifferent and have no fondness for music, in neurasthenics and in some animals. The cardiograms were recorded with the Einthoven string galvanometer. The pulse and pressure were obtained with a Tycos and a modified form of Erlanger's sphygmomanometer, and the music from phonographic records. The pieces of music were first, Tschaikowsky's Symphonie pathétique, characterized by its tragic, slow, minor movements; second, the toreador's brilliant description of the bull fight from Carmen; and third, the National Emblem, a stirring rhythmic march by Sousa. While listening to the symphony, the average effect is a slight decrease if any of the "P. P." wave, and therefore a relatively slight increase in the pulse rate, and also that the amplitude or

E. M. F. of the "R." wave is increased. From two to ten minutes after the music has ceased, the pulse rate and the E. M. F. have increased considerably, but the systolic and pulse pressure have fallen. Consequently the minor tones of the symphony records caused an increase in cardiac activity and action current, but a fall in blood pressure.

Toreador's stirring song produced a different picture of cardiograms. The pulse rate was accelerated and the E. M. F. or amplitude of "R" wave became less as soon as the song was heard. This is graphically shown in the decrease of the "P. P." and "T. P." phases, and height of the "R" wave in cardiograms obtained while listening to the song. The after effect was increased systolic and pulse pressure and pulse rate, but decreased action current. It seems, therefore, that this kind of music had a stimulating effect on the circulation by increasing the blood pressure and pulse rate while lessening the action of current of the ventricular contraction. The effect of the inspiring rhythmical tones of the National Emblem, was a slower pulse rate, a longer pause or "T. P." wave, and an increase of not only the systolic and pulse pressure but also the action current of the ventricular contraction. It seems that this music had its stimulating effect on the vagus, and that this as well as other kinds of music may have an influence on the system in other respects. The authors suggest that it is possible that a careful selection of music may be a beneficial aid in the treatment of nervous disturbances.

30. **Placental Transmission of Creatinin and Creatin.**—Hunter and Campbell found that the concentrations of creatinin and creatin in the maternal plasma differ little, if at all, from those of the same substances in the fetal. Parturition is accompanied normally, although perhaps not invariably, by a temporary rise in blood creatinin. This effect appears to be illustrated most strikingly among primiparas. The creatin content of the plasma at parturition corresponds with that found normally in association with creatinuria. The concentration of creatin in the whole blood is generally greater in the fetus than in the mother; but the concentration in the corpuscles, as in the plasma, is practically the same in both. The concentration of creatin in the corpuscles of parturient women is greater than in those of nonpregnant women or of men. It would appear that pregnancy is accompanied by a special accumulation of creatin in the corpuscles.

34. **Growth Producing Substances in Typhoid Bacilli Cultures.**—According to Pacini and Russell the typhoid bacillus, in growing, produces vitamin which can be isolated and identified by proper biologic methods. The bearing on the effect of the same on the general metabolism of typhoid patients, and indications of a scientific basis for new methods of feeding these cases, are under investigation.

41. **Studies in Calcium and Magnesium Metabolism.**—The daily urinary calcium and magnesium excretion of nine healthy adults on a diet of natural foods containing more magnesium than calcium ranged from 0.05 to 0.25 gm. calcium and from 0.03 to 0.15 gm. magnesium; on a diet having more calcium than magnesium the limits were 0.12 to 0.47 gm. calcium and 0.05 to 0.23 magnesium. In the nine persons in general more calcium than magnesium was excreted in the urine; or if such was not the case the usual calcium-magnesium relation could be promptly brought about by ingestion of milk. The urinary output of both calcium and magnesium was increased by consumption of milk. Dried skimmed milk was practically as effective as raw milk in influencing the urinary alkali earth excretion. The urinary calcium excretion was always increased after taking calcium lactate. The urinary magnesium excretion was apparently not affected by the introduction of magnesium citrate. Comparable quantities of calcium salts, represented by calcium lactate, were not as efficacious as milk in producing increased urinary excretion of lime. Attention is called to the variation in the relative amounts of alkali earths excreted through the kidneys by different persons. The quantities bear no fixed relation to body weight, but presumably are influenced not only by the diet but also by the tissue reserves, particularly in the bones, of the persons.

48. **Determination of Sugar in Urine.**—The procedure adopted by Benedict and Osterberg is an adaptation of the colorimetric

procedure of Lewis and Benedict for determination of sugar in the blood. Their work with the Myers' modification has convinced us that results by this method are too high (due partly to imperfect removal of creatinin). The method presented is considered under two divisions: (1) the preliminary precipitation of interfering substances from the urine, and (2) the determination of the sugar in the filtrate. They have found that urines can be almost entirely freed from the substances enumerated above by single precipitation with excess of mercuric nitrate in presence of a slight excess of sodium bicarbonate. After subsequent removal of the mercury with zinc dust the filtrates are water-clear, and contain almost no measurable nitrogen, or at least not more than 0.1 mg. per c.c. No creatinin can be detected in the filtrates. The special reagents used in the final method for the determination of sugar in urine are: 1. Mercuric nitrate solution. It is prepared as follows: To 160 c.c. of concentrated nitric acid in a beaker add in small portion, 220 gm. of mercuric oxid. When all is dissolved heat the mixture to boiling, cool and add 60 c.c. of 5 per cent. sodium hydroxid solution. Make up to 1 liter and filter. Keep in a brown bottle. 2. Picrate-picric acid solution. To 500 c.c. of 1 per cent. sodium hydroxid solution in a liter flask or stoppered cylinder add 36 gm. of picric acid, and about 400 c.c. of hot water. Shake occasionally until the picric acid is dissolved, cool and dilute to 1 liter.

The procedure for the sugar determination is as follows: Measure 15 or preferably 20 c.c. of urine into a 500 c.c. beaker and add an equal volume of the mercuric nitrate solution and mix. Then add solid sodium bicarbonate in moderate quantities, with gentle shaking, until frothing ceases and the mixture reacts alkaline to litmus paper. Filter at once through a dry filter into a small dry flask or beaker. To the perfectly clear filtrate add a pinch of zinc dust and 1 or 2 drops of concentrated hydrochloric acid. Shake and let stand for about five minutes. Filter through a small dry filter into a dry test tube or small beaker. From 1 to 4 c.c. of this final filtrate (the volume to be used depends on the sugar content of the original urine, from 0.5 to 2 mg. of sugar is the quantity desired) are measured into a large test tube, which should be graduated to indicate 12.5 and 25 c.c. Where less than 4 c.c. of filtrate have been used enough water is added to make exactly 4 c.c. and 1 c.c. of 20 per cent. (anhydrous) sodium carbonate solution is added. Four c.c. of the picrate-picric solution is now added, the tube plugged with cotton, and placed in boiling water for ten minutes. The tube is then removed, cooled to room temperature with the help of running water, and the contents are diluted with water to the 25 c.c. mark, or to 12.5 c.c. if the quantity of sugar present was much below 1 mg. The colored solution is then matched (within half an hour) in a colorimeter against a standard prepared by treating 1 mg. of glucose in 4 c.c. of water, just as the final filtrate was treated; or against a permanent standard of picramic acid solution or potassium dichromate.

Benedict and Osterberg have found that the best permanent standard is to be prepared from pure picramic acid, together with some of the picrate-picric acid solution used in the determination. This standard solution has the following composition: To 105 c.c. of exactly 0.01 per cent. picramic acid solution in 0.02 per cent. sodium carbonate solution, add 0.5 c.c. of 20 per cent. sodium carbonate solution, and 15 c.c. of the picrate-picric acid solution. Then dilute to 300 c.c. with distilled water. Starting with pure picramic acid, the depth and quality of the color of this solution duplicate very exactly that obtained from 1 mg. of glucose dissolved in 4 c.c. of water, treated as described for the final urine filtrates, and the colored solution diluted to 25 c.c. The standard in the colorimeter should be set at a height of 15 mm.

59 Ordinary Brown Mice Substitute for White Mice in Pneumococcus Grouping. O. J. Walker and W. J. Bruce, Oklahoma City. —p. 434.

52. **Allergic Phenomena and Cause of Death.**—From the experimental evidence obtained by Pelz and Jackson are certain that on the injection of the antigen in highly sensitized spinal dogs, the asphyxia produced by the acute bronchial constriction may readily be the cause of death, and that the phenomenon occurs with the liver and other abdominal viscera wholly removed from the circulation. The phenomena occur in those dogs sensitized to egg white equally as well as in those sensitized to normal horse serum. The bronchial and blood pressure changes produced in acute anaphylactic shock bear a striking and almost complete resemblance to those produced by certain opium alkaloids, such as codein, heroin, peronin, etc. For producing relaxation of the bronchioles, and aiding in recovery in acute anaphylactic shock, epinephrin is the most dependable substance, but to produce the best effects the drug must be injected early, before the bronchoconstriction has had time to become too intense.

53. **Studies on Immunity.**—The authors show that true antigens (that is, antigens which contain the etiologic factor of the disease, emulsified or autolyzed) will work only where there is a polymorphonuclear leukocytosis present. While tuberculosis is a disease presenting a lymphocytosis, it will fix the complement with a specific antigen, which, however, is not a bacterial emulsion, but a heated egg medium culture containing small amounts of lipoid. Tissue extracts of mammals, birds, reptiles and fishes may serve as useful antigens for the diagnosis of syphilis. If normal urine is added, the complement of the hemolytic system is affected without the presence of a specific antigen. The presence of hemolysis in the test of the fourth group indicates either some type of affection of the kidney (even when no albumin or casts are demonstrable) or pregnancy, the two conditions frequently being separable by the clinical history of the patient. The absence of hemolysis in a hemolytic system to which urine is added speaks against the condition of pregnancy. In complement fixation without an antigen, reaction affecting the third tube (which serves as control tube and should not hemolyze) speaks for nephritis, rather than pregnancy.

54. **Meningitis at Camp Greene.**—Statistics at hand indicate that there have been between 5 and 7 per cent. of carriers in Camp Greene. In the only organization which made use of systematic nasal sprays since the first of the year not a single case developed, and in those organizations in which sprays were resorted to after the appearance of the disease no other cases appeared. Woolley says that this may be merely coincidental, but when one discovers that also following the adoption of sprays the total sick rate falls, especially that due to respiratory diseases, and bears in mind the current conception that the meningococci inhabit the nasal passages, one comes to have a very healthy respect for dichloramin-T as an agent for the prevention of diseases of upper respiratory tract origin.

55. **Intravenous Use of Mercuric Iodid.**—Rowe claims that red mercuric iodid in combination with an equal amount of potassium iodid can be injected in solution into animals intravenously with comparative safety if reasonable care is exercised in the manner of injection and in the size of the dose injected. It is very little if any more toxic than mercuric chlorid, safer for intravenous use, and of greater germicidal efficiency.

58. **Differentiating Polychromatic Toluidin-Blue Stain.**—The preparation of the stain used by Barron is as follows: toluidin-blue, 1.0; potassium carbonate, 1.0; distilled water, 400.0. Boil solution in glass beaker until it is reduced to

300 c.c. Cool; than add: toluidin-blue, 2.0; sodium chlorid, 3.0; glacial acetic acid, 12.0; alcohol, 15.0. Stir mixture until ingredients are completely dissolved. It is ready for use at once, and can be used over and over again. It does not precipitate and keeps indefinitely. The following technic is employed in staining frozen sections for rapid diagnosis. A piece of tissue which is not more than 3 mm. in thickness is dropped into boiling 10 per cent. formaldehyd solution for about one minute. Fresh tissue without hardening may be used in many cases but the sections are more difficult to handle. The tissue is cut with the freezing microtome, and the sections are placed in a dish containing physiologic salt solution. The sections are quickly straightened out and carried over into a small dish of the stain where they are left for about fifteen seconds. They can be left for a much longer time without overstaining. The sections are then transferred to another dish of physiologic salt solution where they are rapidly washed for a few seconds to remove the excess of stain, and then are at once mounted in the same solution on a slide, and a coverslip applied. The section is now ready for examination. The entire process, from the time the section is cut to the completed preparation for microscopic study, need not take more than one minute in most instances.

Journal of Nervous and Mental Disease, Lancaster, Pa.

April, 1918, **47**, No. 4

60 Influence of Angle of Section on Measurements of Cortex Depth and on Cyto-Architectonic Picture. S. T. Orton, Philadelphia. —p. 241.
61 *Unilateral Ophthalmoplegia; Report of Case Due to Carotid Aneurysm. H. Viets, Boston.—p. 249.
62 *Medical Treatment of Exophthalmic Goiter; Special Reference to Use of Corpus Luteum Extract. H. H. Hoppe, Cincinnati.—p. 254.
63 *Intracranial Treatment of Paresis. H. A. Cotton and W. W. Stevenson, Trenton, N. J.—p. 262.

61. **Unilateral Ophthalmoplegia Due to Carotid Aneurysm.**—An unusual case of aneurysm of the right intracranial carotid artery is reported by Viets. The symptoms were: complete ophthalmoplegia with sensory disturbances of the trigeminus. The aneurysm was seen at operation. No etiologic factor was found. Rupture has not taken place after seven months of symptoms. The author has failed to find in the literature a report of a similar case.

62. **Medical Treatment of Exophthalmic Goiter.**—Hoppe has treated about twenty cases of exophthalmic goiter. The ordinary Forchheimer treatment was attended with only indifferent success. The combination, however, of quinin hydrobromate, extract belladonna with the extract corpus luteum was found to be rapidly beneficial in nearly all the cases and the improvement was usually so rapid and so marked, in a few days to a week, to convince Hoppe that rest, diet, hygienic measures, all of which he had used for twenty years before, could not account for the result, but that the corpus luteum was the active therapeutic agent.

63. **Intracranial Treatment of Paresis.**—The authors make use of two methods—the method of Hammond and Sharpe and the method of Wardner. The difference between these two methods is that in the former the serum is introduced into the ventricle and in the latter it is introduced under the dura. Six or more treatments are given by the former and then several of the latter, or alternating them. The authors have modified the methods of intracranial treatment, both the intraventricular and the subdural, so that the time necessary for these operations has been materially reduced. They do not give a general anesthetic, but merely cocainize the scalp.

The results of four years' experience in the treatment of cerebrospinal syphilis are summarized as follows: 1. The intracranial (either the intraventricular or subdural) method is the most efficacious method in the treatment of paresis and should be the method of preference. 2. The intraspinal method is the most efficient one for the treatment of tabes and syphilitic meningitis. 3. Arsphenamin is the best drug for the treatment of cerebrospinal syphilis and preferable to the diarsenol brand and other substitutes. 4. The mercurialized serum of Byrnes is of doubtful value, as it is not of sufficient potency to destroy the spirochete. 5. The success of any method of treatment depends on the stage in which the disease is treated, and the earlier the stage the better the outcome of the treatment. Therefore, if possible, the disease should be diagnosed in the preparetic stage or as soon as symptoms are present. 6. Every case of syphilis should have an examination of the spinal fluid at frequent intervals after all symptoms of the acute stage are lost, especially if the blood Wassermann remains positive after sufficient treatment has been given. 7. All cases of paresis can be arrested and possibly cured if treatment is begun early enough. 8. Physicians should be taught to recognize the importance of an early diagnosis and trained to make such a diagnosis, so that cases can be referred for treatment before the process has gone too far for treatment to be effective. 9. The treatment of paresis should be undertaken by all institutions for the insane, and all cases treated, as it is a difficult matter to decide whether a given case has reached the stage when treatment would be useless.

70. **Neurocirculatory Asthenia.**—Lewis points out that this is not a new and strange syndrome, but a condition frequently seen in civilian practice in a milder form after an attack of grip, typhoid, severe tonsillitis, or scarlet fever. The general type of patient is one who is readily exhausted, physically and psychically. His subjective symptoms are referable chiefly to the circulatory apparatus and nervous system. He complains not constantly perhaps of dyspnea on effort, of feeling generally "shaky," of pains in the left chest, of palpitation, headache, dizziness and faintness. He is usually susceptible to cold and becomes readily fatigued. He is often quite aware of his tremor and complains of the fact that he perspires too profusely. Lewis suggests a new name for this condition, neurocirculatory asthenia. He suggests further that all medical officers of the American forces should learn to recognize the clinical picture of this syndrome, and a certain selected number should have the opportunity of studying such cases and of learning by actual experience to employ a system of graduated exercises as a therapeutic measure and as an aid to categorization. To limit the occurrence of this disorder in a prophylactic way it is suggested that: (*a*) Measures be taken for the early recognition of cases of neurocirculatory asthenia, that is, at the time men are called to service and at the training camps. (*b*) Men who are seen to flag or show signs of breathlessness by their drill instructors should be reported to the medical officer and thoroughly overhauled from the point of view of this syndrome at an early date. (*c*) The period of convalescence after infectious diseases be made sufficiently long, and, after complete recovery, the soldiers be gradually hardened before returning to full duty. It is strongly recommended, above all, not to transport soldiers suffering from this disorder overseas for active service, as it is now known that their period of service on full duty is short.

72. **Foot Strapping.**—A method of strapping with adhesive plaster for foot strains and for pronated and flattened feet is submitted by Morton.

4. **Phlebotomus Fever.**—An outbreak of phlebotomus fever (sandfly fever) occurred in a squadron of yeomanry on outpost duty in mid-Egypt in the middle of the summer of 1917. The post was on the western edge of the cultivation, and Hartley was in medical charge of the unit. Of the total strength, 86.4 per cent. were infected. The incubation period was from four to seven days. The onset was very sudden, accompanied with severe malaise, headache, and suffusion about the eyes and postorbital pain. Pain in the lumbar region was generally intense, and pain and cramp in the limbs occurred. Constipation was nearly always present and profuse sweating. The temperature rose quickly to 102.5 or 103, and on a few occasions to 105. After twenty-four hours the pyrexia diminished, and at the end of three days, fell to normal. The pulse was not correspondingly accelerated—it was seldom above 80; it became soft and weak and the cardiac condition required attention. The suddenness of the onset was the marked feature. Subsequent debility was a marked feature considering the shortness of the acute stage, but many managed to recover sufficiently to return to light duty after fourteen days.

9. **Cardiac Infection in Childhood.**—Among 524 children, all under 12 years of age, examined by Poynton, the following conditions were present: heart disease in 293; chorea in 268; arthritis and arthritic pains in 267; sore throats in 147; nervous manifestations other than chorea in 80. Two important groups are recognized by the author: 1. Cases with sore throat, arthritis, and morbus cordis. 2. Cases with chorea and morbus cordis.

10. **Shell Shock and Neurasthenia.**—The mental symptoms noted by White in over 800 cases of shell shock and neurasthenia have occurred in the following order of frequency: confusional, melancholic, delusional, stuporose and maniacal. In many patients the memory was impaired for recent events and day to day actions and happenings, and there is a blank in regard to the incidents of their shell shock period. Memory for recent events to daily life, however, improves as the case progresses to recovery. The moral tone of the individual may be changed for the worse, and this change of character may be out of all proportion to the severity of the original shell shock. With it there may be altered feelings, affections, temper, and habits generally. From the medicolegal standpoint this morbid mental state is very important in regard to responsibility, and must be duly recognized. The patients with acute symptoms are kept in bed, but made to get out and walk a few steps every day, when able. Absolute quiet and fresh air (veranda life if weather permits) are essential, and no stimulants can be allowed. The milder cases with tremors and those with hysterical or pithiatic, and mild hystero-epileptic symptoms improve under bromid and valerian, nux vomica, arsenic, and other nerve tonics, but

environment and habits of life play an even more important part than drugs. Carefully controlled employment of mind and body is most necessary to expedite recovery and divert the patient's thoughts. He must be outdoors whenever the weather permits, engaged in gardening, wood-cutting, and outdoor sports and games, and when indoors, in workshops, and in taking part in the various amusements of home life. Clear, bracing air is very important.

11. **War Psychoses in Cases of Shell Shock.**—The following were by far the commonest symptoms noted by Eager in an examination of over 4,000 cases: amnesia, melancholia, mental confusion, delusion· and hallucinatory disturbances. The condition of stupor was also met with, but was not so common as the aforementioned, and in some instances the sequence of events showed that cases which had been admitted to the hospital originally as definite cases of shell shock, have subsequently passed into a neurasthenic condition, which again has not improved, but drifted into states closely resembling dementia praecox. Retardation of thought was a pronounced symptom in the majority of cases; mutism and deafness were also met with. Associated with the above symptoms were headache, insomnia, terrifying dreams, general nervousness, and varying strange sensations in the head. As regards the physical signs, the deep reflexes were always very much increased, tremors were present almost universally in the tongue and outstretched hands, and the pupils were generally dilated. Frequently patients complained of throbbing sensations in the precordia, clamminess of the skin, and appeared before one as highly strung and emotional.

17. **Tartar Emetic in Treatment of Malaria.**—The observations recorded by Hughes were made in the spring of 1917 at an Indian hospital in German East Africa. The cases, except three, were not chosen, some being severe and some slight. The exceptions were three cases of blackwater fever, which after the blackwater had disappeared developed fever with parasites in the peripheral blood. There being some doubt as to the advisability of administering quinin except in small doses to such cases, tartar emetin intravenously was tried. One case had a relapse of blackwater after an intramuscular injection of 10 grains of quinin bihydrochlorid. In all, thirteen cases were treated, ten of subtertian, two of benign tertian, and one of quartan. Two of the subtertian cases and the quartan case were blackwater convalescents. The drug was injected in 2 per cent. solution in normal saline by means of a 10 c.c. syringe into a vein at the bend of the elbow, the quantities administered varying from 3 to 14 centigrams, given as a rule every second or third day. At first the smaller quantities were used beginning with 3 or 4 centigrams and working up to 8, while in later cases 10 centigrams was given as the initial dose and increased to 14 centigrams. With the latter dosage toxic symptoms manifested themselves, coughing and vomiting being sometimes troublesome. Care had to be taken that none of the solution escaped into the tissues surrounding the vein. This happened on two occasions and gave rise to much local pain, and eventually in one case to suppuration. During the administration of tartar emetic all quinin was withheld, except in one case. So far as conclusions can be drawn from the few cases here mentioned, the results would tend to show that tartar emetic is not a cure for subtertian malaria, at least in nontoxic doses. Curative effects were observed in varying degrees only when doses toxic to the patient were given. This bears out Greig's statement that tartar emetic appears to be rather a general protoplasmic poison than a specific poison for the malarial parasite.

31 *Historical Case of Rickets. C. Burland.—p. 391.

26. **Impetigo Contagiosa as Cause of Nephritis.**—Stiell reports five cases of acute nephritis resulting from typical impetigo contagiosa. From an analysis of these five cases, it seems probable that an acute streptococcal impetigo is capable of producing an acute nephritis, every bit as severe as that following an ordinary attack of scarlatina. Stiell does not suggest that every case of impetigo subsequently develops nephritis as a complication, but, at the same time, he does consider that the risk of this occurrence, even in efficiently treated cases, is quite as great as in scarlatina, and that impetigo is frequently and explanation of many of the sudden and acute cases of nephritis, occurring in children, for which formerly there has been no satisfactory explanation. He suggests that in a similar manner it is possible that many of the cases of so-called "trench nephritis" in soldiers are, in fact, a complication either of an impetiginous pediculosis or an impetiginous scabies.

31. **Historical Case of Rickets.**—Burland republishes an account of the medical examination of the remains of Princess Elizabeth, daughter of King Charles I., who died at Carisbrook Castle, September 8, 1650, written by E. P. Wilkins in 1856.

32 *The Blood in Typhus. D. Danielopolu.—p. 49.
33 *Aortic Insufficiency from Air Concussion. A. Cramer.—p. 66; J. Brossard and J. Heitz.—p. 71.
34 *Pulsus Alternans and Digitalis. Carpentier.—p. 79.

32. **The Blood in Typhus.**—More or less pronounced leukocytosis was evident in the first week in 62 per cent. of the 250 typhus patients examined, and in the second week in 96 per cent. In the severer cases the leukocytes numbered from 20,000 to 128,000, the leukocyte curve thus serving as a reliable index of the toxic action of the disease. More than 20,000 indicates an unfavorable outcome. A leukocytosis rapidly jumping from 25,000 to 50,000 and 90,000 served to differentiate typhus in one puzzling case in which the temperature dropped early to normal and below. The hyperleukocytosis also revealed associated typhus in some typhoid cases. Any complicating inflammatory process in typhus is liable to increase the leukocytosis, but this has no bearing on the prognosis. The blood shows constantly mononuclear leukocytes with protoplasm staining intensely blue, excentric nucleus, and no granulations, but this type of "plasmatic cells" are found in certain other infectious diseases, although less numerous.

33. **Aortic Insufficiency from Air Concussion.**—Cramer's patient presented the signs of severe aortic insufficiency which had developed after the young soldier had been flung several feet into the air by the air concussion from a bomb. He had previously been healthy and had always escaped the diseases which predispose to heart disease, but he is now one of the *grands blessés médicaux* of the war.

Brossard and Heitz report two similar cases of traumatic aortic insufficiency following shell shock. In one the valvular symptoms were pronounced at once; in the other they developed in the course of a few days. The wind from an exploding bomb, without fall or contusion, even with the man already flat on the ground, we know is capable of inducing hemorrhage in the nerve centers or rupture of both lungs as in Sencert's case, injury of the optic layer, as in Léri's case, and it was evidently responsible for the laceration of the aortic valve, the most fragile of all the valves, in these three cases.

34. **Pulsus Alternans.**—Carpentier compares recent works on pulsus alternans with Windle's study of the effect of digitalis on alternance of the pulse in seventy cases. None of Windle's patients survived for more than three years, but some improvement under digitalis was constant. The pulsus alternans was never accentuated; it generally became attenuated under the digitalis and during the following two or three weeks, except in the cases with arteriosclerosis. Windle does not seem to have had his attention called to the frequency of syphilis in the antecedents in cases of pulsus alternans. Some others have reported syphilis certain in nine and probable in four others in forty cases of alternance, or 15 per cent. in other groups. In Windle's experience, the pulse never assumed the alternans type during treatment with digitalis except in two cases, and in one of these it subsided under the continued use of tincture of digitalis. He pushes it until nausea or coupled rhythm appear, giving from 12 to 28 gm. of the tincture (*Quarterly Journal of Medicine,* 1917, **10,** No. 40), according to the severity of the case. The effect is exhausted in two or three weeks, and the digitalis must then be resumed.

41 *Transactions of the Third Conférence Chirurgicale Interalliée. —p. 1.

35. **The Indications with Multiple Wounds.**—Okinczyc and Clavaud describe twenty-three cases in which the large number of wounds seemed to forbid any attempt at operative measures, but in which they succeeded in enlarging the limits of the possible and saving life in many of these nontransportable cases. The decision as to whether to operate or not should be made in from thirty to forty-five minutes during which time heat and other measures to combat shock are applied. Heating longer than this predisposes to hemorrhage. If the radial pulse is 120 or over or is imperceptible at this time, there is little hope from any intervention. Two of the men had no perceptible radial pulse for twenty-four or thirty-six hours, but then it reappeared and the men recovered after the amputation done then. Roentgenoscopy is indispensable to show the number and location of the multiple projectiles. In eleven cases of abdominal wounds with numerous wounds elsewhere, three of the men recovered after a thorough abdominal operation. Laparotomy was done in one case merely to relieve the atrocious pain from blood and bowel content loose in the abdomen. The man died the next day, but without suffering further pain. Antitetanus serum should be given once a week for three weeks if there are still projectiles left in the tissues. The bleeding wounds should be attended to first, and if there are several on one limb, the upper one first. Injured joints and bones should be given special attention to ward off complications. Amputation of a limb with several grave wounds does away with multiple sources of shock and almost certain infection. Each one of these *polyblessés* cases is a new problem in itself, and it takes courage to attempt the impossible, knowing that the outcome at best will probably be vicious stumps or badly healed wounds.

36. **Secondary Suture of Wounds.**—Ferrari and Delotte analyze their experiences with the Carrel and other methods for preparing a wound for suture. They have learned never to suture a wound that looks bad, even if the bacteriologic findings are favorable. The findings would not be so favorable if every spot of the entire area of the wound could be tested. On the other hand, when the wound looks good and there seems to be a good cellular reaction, they do not hesitate to suture even with five or six diplococci to the field. They estimate the cellular reaction by the number of blood cells that are not polynuclear whites, and they feel safe in suturing when from 15 to 30 per cent. of the leukocytes are mononuclears. They suture without draining or with only a filiform drain, ready to clip one or two of the hairs if need arise in the next few days. In five cases they preceded the suture with an intravenous injection of a polyvalent serum against the agents of inflammation and suppuration. The suture healed smoothly in each case. The main thing in suturing is not to leave any of the walls not in contact; any spaces left are liable to fill up with blood. The hematoma is the greatest and most frequent danger, and hence we cannot be too careful in insuring hemostasis. Fever the same or the following day after suture is often due merely to hematoma, which can be easily evacuated, and healing proceeds undisturbed, especially when the cavity is rinsed out with ether poured in through the drains or between the stitches. The other dangers are the cutting through of the suture threads where the skin is too tender; and gangrene of the flap drawn too tight.

37. **The Nephritis Service.**—The soldiers with pathologic albuminuria are sent to the service arranged for this purpose by Laubry and Marre, and they describe the methods for diagnosis and treatment, with the outcome, in 200 cases of nephritis. Each man has his "renal certificate" on which are recorded the curve of urine output, the chemical and microscopic findings in the urine, the findings in regard to chlorids, with and without alimentary tests, the urea content of the blood, and the Ambard coefficient, also the response to the methylene blue test of the permeability of the kidney, and the arterial pressure. If the man recovered enough to return to the ranks, the regimental medical officer was sent confidentially a copy of this *fiche rénale.* If the man was unfit for duty, it served as a basis for his discharge from the army.

41. **Surgical Conference.**—Some of the conclusions at this third conference were mentioned in these columns May 18, p. 1520. There were ten American army medical officers present, seven British, seven Belgian, eight French, two Japanese and one Canadian, Italian, Portuguese and Serbian. This bulky volume of 365 pages with twenty-four plates reproduces the communications presented by the various speakers, with the discussions. A fourth conference has been held since, and the conclusions adopted are summarized below, Abstract 69.

43 The Midwives of France. P. Bar.—p. 385.

42. **Social Problems Affecting the Mother and Child.**—Bar remarks that the war has deprived the medical schools and the hospitals of most of the men devoted to scientific research, while, on the other hand, the tragic events of the war render more than ever necessary the study of medicosocial questions involving the very life of the nation. Hitherto the indifference of too many of the politicians and the neglect by too many officials has left these questions unsolved as of negligible importance. He urges that a systematic campaign must be undertaken against the plagues which are the capital causes of depopulation: syphilis, tuberculosis, alcoholism, voluntary birth control, etc. He then reviews and comments on the discussions held recently in various scientific societies, the Prison Society, the decrees

of the minister of munitions and the laws enacted affecting mothers and infants and prospective mothers, at home and in the factory.

47 Spontaneous Alteration of Atoxyl. François.—p. 255.
48 *Film Treatment after Mastoid Operation. Daure.—p. 258.

44. **Toxicity of Eggs.**—Linossier remarks that there seems to be a tendency now to disparage eggs as liable to prove toxic under certain conditions, even when quite fresh. He has made a special study of the subject for several years, having published an article on it in 1905. His present conclusions are to the effect that there is undoubtedly some substance in eggs which has a toxic action on certain predisposed persons. The predisposition is often congenital. When it is acquired, it seems to be connected with liver and intestinal disturbance. The toxic substance is probably a toxalbumin, and it is destroyed by heat. All that is necessary is to coagulate all the albumin in the egg, in the yolk as well as in the white. He remarks that the reason why cooked egg seems to be harder of digestion than raw, is because it is digested in the stomach, while the raw egg is passed on undigested, and is not hydrolyzed until it reaches the intestines. He warns against prolonging the action of heat after coagulation is complete, as the harder the coagulation, the more difficult the digestion by the gastric juice. He insists that there are no grounds for denying eggs in liver diseases, but with a tendency to gallstones, it is wiser not to allow more than one egg a day, so as not to increase the cholesterolemia. Well cooked eggs can be allowed with albuminuria, but persons with interstitial nephritis and hypercholesterolemia had better refrain from eggs.

46. **Vaccination of Pacific Islanders Against Typhoid.**—Summarized in Paris Letter, page 1320.

48. **Film Treatment After Mastoid Operation.**—Daure refers to radical petromastoid clearing out of diseased tissue, the aftercare of which has always been a tedious and risky business. The film treatment simplifies it very much and reduces the risks. The cavity is half filled with the paraffin mixture at 70 C.; a cord is introduced in the midst of the paraffin. It is left undisturbed for five or six days, and then the solid block of paraffin is lifted out by the cord and a fresh paraffin dressing applied, after the cavity has been dried with cotton or hot air. When the conditions were such as to forbid the film treatment, he applies the Carrel irrigation technic until the field is ready for the film dressing.

53 Purulent Pleurisy from Typhoid Bacilli. Tavernier, Serr and Brette.—p. 123.
54 Hospital Apparatus for Subcutaneous Injections of Quinin. J. Baur.—p. 127.

49. **Pathognomonic Sign of Abdominal Aortitis.**—Mougeot has noticed that the femoral pulse beat at the root of the thigh was felt from a fortieth to a twentieth of a second before the radial pulse beat in cases of abdominal aortitis. With aneurysm of the lower aorta, the femoral pulse lags behind the radial pulse, but with abdominal aortitis the femoral pulse is advanced before the radial pulse. As this finding was constant in the fifty cases of abdominal aortitis tested for this sign, he thinks that it may be regarded as pathognomonic. In all other forms of disease of the aorta, sparing the abdominal portion, the radial and femoral pulse beats are synchronous.

50. **False Bradycardia.**—The pulsus bigeminus with extrasystoles was only 44 but the heart beat was 88, when the young man was reclining. When sitting up or standing, the radial pulse and the heart beat were both 80 and regular. In the reclining position the oculocardiac reflex did not modify either, but, seated or standing, both were retarded by eight or ten beats. Epinephrin and atropin accelerated both heart and pulse beat. A nervous origin for the bradysphygmia thus seemed beyond question. But the sympathetic system and not the pneumogastric seemed to be the one involved

51. **Typhoid Genital Lesions.**—Faroy reports three cases of typhoid and paratyphoid orchitis and epididymitis, with urethritis in two of the cases. The onset was sudden, intense pain in one testicle, occurring in convalescence or as defervescence impended. The genital complications subsided completely in eight or ten days without entailing suppuration or atrophy. The urethritis was revealed merely by a purulent drop squeezed out of the passage. There was no history of and nothing to suggest gonorrhea in any of the cases. The urethritis preceded and was probably responsible for the orchitis.

52. **Test for Quinin in Urine.**—An aqueous solution of picric acid added to fluids containing traces of salts of alkaloids, especially quinin, forms a very fine, light precipitate of picrates, causing opalescence or turbidity in the fluid or sedimentation A set of ten test tubes are prepared with normal urine plus progressive amounts of quinin, from 0.01 to 0.10 gm. per liter. To each tube is added 5 c.c. of 1 per cent. solution of picric acid or Esbach reagent. This gives a set of standards with which the turbidity of the urine to be tested is compared. All must be well shaken up at the time, and five minutes contact be allowed. The urine must be free from albumin and other alkaloids, etc. Uric acid crystallizes on the walls of the tube, without causing turbidity.

55 Soldiers' Cemeteries. L. Bosredon.—p. 55.
56 *Acute Nonsuppurating Encephalitis. Creyx.—p. 62.
57 *Pneumococcus Meningitis. H. Mallié.—p. 67.

56. **Nonsuppurative Encephalitis.**—Creyx remarks that what we call meningeal symptoms in reality are not meningeal, as the meninges in themselves are not capable of inducing such symptoms. They manifest their lesions by the reaction in the parts which they inclose. In an acute case described, a young woman had had fever and diarrhea for two weeks and then coma developed, with slight trismus and slight contracture of the arms and exaggeration of the tendon reflexes. The legs were relaxed, the tendon reflexes abolished. There was no Kernig sign nor trace of hyperesthesia or convulsions. Lumbar puncture released limpid fluid under considerable pressure. There was nothing to suggest poisoning, and the temperature kept very high. The woman died the third day after the onset of the coma, and necropsy revealed merely acute encephalitis without suppuration, as the only lesion accompanying the septicemia. The bacteriologic findings were negative, but the examination was not very thorough. The irregularity in the distribution of the lesions entails remarkable variety in the symptoms, very different from the systematic phenomena noted with chronic disease of the nerve centers. The acute encephalitis may subside without leaving a trace, but it usually leaves some definite sclerosis at certain points or in certain fibers, and these acquire a definite character. Acute nonsuppurative encephalitis has been observed in connection with malaria, syphilis, rabies, poliomyelitis and tuberculosis, as well as with streptococcus, staphylococcus and pneumococcus infection. Suppuration is the rule with mixed infection According to the localization of the inflammation, the symptoms are delirium, convulsions and coma, with a diffuse process, but with focal lesions they are localized. The age makes a difference: in the fetus, Little's disease results; in children, cerebral paralysis or symptoms from the sequels of the inflammatory process, possibly typical insular sclerosis.

57. **Pneumococcus Meningitis.**—Mallié found one case of meningitis accompanying pneumonia in 244 cases of frank pneumonia in a camp of German prisoners. In another case there was pneumococcus meningitis without pneumonia, confirmed by necropsy. **Weill** reported in 1915 a similar case in

a child. He regards the pneumonia as merely a habitual episode in pneumococcus septicemia; it is not a local disease like tonsillitis or phlegmon.

69 *The Fourth Interallied Surgical Conference.—p. 193.

61. **Adhesions Between Pericardium and Diaphragm.**—The functional disturbance is a set of symptoms suggesting angina pectoris. The physical symptom is the disappearance of the apex beat. The roentgen symptom is a shadow at the left side where the heart and diaphragm are soldered together. This triad characterizes adhesive phrenopericarditis. Trémolières and Caussade have encountered twenty cases of this kind. Although the angina pectoris symptoms may be distressing at times, yet they never had serious consequences in their experience.

63. **Urea Content of the Blood and Ambard's Constant.**—Legueu and Chabanier discuss the significance, the clinical application and the import for the prognosis of azotemia and the ureosecretory constant according to Ambard's formula. They have simplified this formula to the coefficient found by dividing the urea content of the blood by the square root of the urea content of the urine brought up to twenty-five per thousand. This coefficient in normal conditions is 0.070. Experience has confirmed, they reiterate, that this coefficient is an absolute and quantitative index of the secreting power of the kidneys. It insures a precision previously unattainable. A dog was submitted to the various tests of kidney functioning with methylene blue, etc. Later the dog was returned to the same investigators for repetition of the tests, without informing them that one kidney had been removed. This was not discovered until the Ambard formula was applied, but this revealed the exact proportion of renal parenchyma that was missing.

Death occurs in nephritis usually during an acute exacerbation of the azotemia. An acute exacerbation may be occasioned by any infectious or toxic state or may follow any operation anywhere on the body. Death from acute azotemia is often mistakenly ascribed to congestion or embolism of the lung or other cause. The organism is producing urea in excess while the kidneys are excreting less than usual. The oliguria may not be extreme, but still the azotemia may reach a fatal height, and here again the Ambard formula reveals the true state of affairs. *It is particularly useful when applied to the urine from each kidney separately when it is a question of nephrectomy.*

64. **Cancer of the** **ectum.**—Desmarest gives an illustrated description of the me hod for removing a cancer in the lower half of the rectum w thout loss of the sphincter of the anus. He works through o incisions, one transverse, across the perineum, and one ongitudinal, over the coccyx. He has [illegible] is method twenty-one cases, and the interval of away with [illegible] since th first case enables him to speak con- infection. Ea the super r advantages of this technic. There problem in itselırrence ir only two of his first series of seven- sible, knowing tl [illegible] the one of these soon after the operation. vicious stumps or l dly come, with the natural anus functioning, shows the superiority of the method, he says, over others which require an artificial anus.

67. **Gastroptosis.**—Pauchet emphasizes that gastroptosis must not be considered a purely local lesion, such as can be cured by an operation. There is always a complex pathologic condition, insufficiency of the glands in the abdomen (liver, suprarenals, etc.); degeneration of tissues, and unstable nervous system. Persons with gastroptosis may have to be treated for months and years to correct each of the disturbances depending on these various causes, with liver and suprarenal organotherapy, physical culture, outdoor exercise, psychic reeducation, massage and general hygiene. It requires a kind of abdominal orthopedics with the cooperation of the surgeon, the physician, the masseur and the physical culture trainer. He describes the operation he has found most effectual to bring the stomach and transverse colon into their proper place. He sutures the transverse colon to the lower margin of the stomach, and then draws up the stomach into the proper shape and size with half a dozen parallel threads quilted superficially the length of the anterior stomach wall, stopping short of the pylorus region and greater curvature. The threads are brought out through the skin and the field is painted with iodin to induce adhesion.

A bandage often gives great relief but it has to be fitted at first under the roentgen rays, and be put on while still reclining in bed each morning. In Pauchet's experience with thirty operative cases, in six the operation alone failed to give permanent relief from all the disturbances. They yielded only when orthopedic principles were applied. Then the patients gain in weight and the general condition improves while the pulse in the erect position is no longer abnormally fast (80 instead of 120 in Leven's case). Gastroptosis is often mistaken for salpingitis if the colon is sensitive, or for wandering kidney if the cecum is distended and painful; for gastric ulcer if there is pain at once after eating, and for chronic appendicitis if there are pains in the iliac fossa. The splashing sound may suggest simple dilatation of the stomach, and if all these can be excluded then a purely functional nervous trouble is sometimes assumed. Operations have often been done on these mistaken diagnoses. Sometimes they merely augment the patient's discomfort and sufferings. Differentiation is based on the history of the case and roentgen examination standing and reclining. The bismuth shows the site and degree of the reducible or permanent kinks in the digestive tract.

68. **Instability of the Thyroid with Neuro-Arthritism.**—Lévi describes the case of a woman of 31 who has presented neuropathic symptoms for many years as well as migraine, recurring lumbago, abdominal ptosis, nasal asthma and varicose veins. Attacks of local congestion in various organs also occurred at times in the lungs or joints or elsewhere, and she had an anaphylactic crisis after injection of horse serum. There were also symptoms of exophthalmic goiter at times while at others the symptoms suggested thyroid deficiency. The thyroid gland varied in size at different times, and Lévi ascribes the whole train of symptoms to this instability of the thyroid gland. This assumption was confirmed by the regulating effect of thyroid treatment. The attacks of hyperthyroidism develop on a basis of chronic hypothyroidism, and hence thyroid treatment, bringing this basic level up to normal, causes the subsidence of the angioneurotic disturbances. This does not surprise those who have witnessed the subsidence under thyroid treatment of urticaria, Quincke's edema and intermittent hydrarthrosis. This case, as also the benefit from thyroid treatment of this woman's sister with somewhat similar symptoms, confirms the necessity for studying the thyroid functioning when these *poussées fluxionnaires* are noted in any organ.

69. **Conclusions Adopted by the Interallied Surgical Conference.**—This fourth conference was held at Paris in March, and the conclusions adopted on the seven subjects appointed for discussion may be partially summarized as follows:

Transfusion of Blood: This is indicated in the first few hours after the wound in case of grave hemorrhage, but in collapse from gas gangrene it has not seemed to benefit, and in shock the indications for transfusion have not been determined as yet. Later posthemorrhagic anemia does not call for transfusion if the general condition is satisfactory. Donors should be tested for agglutinins and classified ready for use, except in emergency cases; fatal accidents have occurred from agglutination of the blood corpuscles by the donor's plasma, but the danger of this is relatively small and may be disregarded at an advanced post, but strict asepsis is indispensable. Transfusion should not be attempted until the bleeding has stopped. It is important to know the quantity of blood transfused. Tests of blood kept for several days have been satisfactory. This method will render great service at the advanced posts during intense military activity. Good results have been obtained with citrated blood, blood drawn into a paraffin ampule, and blood drawn into a syringe.

Trench Foot: Wet cold, long standing or crouching, and secondary infection are responsible for this pathologic condition. It affects soldiers from hot countries more than Europeans, and youth, hyperidrosis and a preceding attack are predisposing factors. The Belgians ascribe the rarity of trench foot in their army to the fact that they have discarded strapped leggings. With preventive treatment, trench foot becomes very rare: facilities for keeping the feet dry and warm, frequent change of units in wet regions, and daily greasing and massaging the feet; changing the shoes, with surveillance not to allow constriction from the puttee straps. Treatment should include a tepid bath and soaping of the foot with a boric acid and camphor soap every two or three days, wrapping it up daily in a large moist boric acid and camphor dressing. Phlyctenas should be opened and if there are eschars they should be merely scarified not to make them bleed but to let the medication act on the subjacent tissues. The eschars should be left to drop off of themselves. No operation should be done unless the surgeon's hand is forced by the general condition except finally to regulate vicious stumps. But preventive tetanus antitoxin should be given every week until healing is complete.

Wounds of the Pelvis: Comminuted fractures of the crest of the ilium require extensive trephining. An intraperitoneal wound of the bladder or rectum requires a laparotomy and suture, and with a suprapubic, extraperitoneal bladder wound, a primary suture of the bladder is in order. With a wound of the side or the base of the bladder the drainage is sufficient and, later, a retention catheter aids in the healing of the urine fistula. Primary emergency cystostomy is required only when there are retention and progressive infiltration around the bladder, or severe hematuria or a foreign body in the bladder. Secondary infection calls for cystostomy with drainage. With an extraperitoneal wound of the rectum, open up the wound, tampon the hole in the bladder, and keep the man constipated. When both bladder and rectum are injured, a retention catheter, ventral decubitus, and micturition in knee-chest position, favor the spontaneous healing of the bladder-rectum fistula, after clearing out the extravesical track of the projectile.

Pseudarthroses: The inevitable cause of pseudarthrosis after a war fracture is the primary destruction of part of the diaphysis. With working men we should aim to secure direct ankylosis between the femur and tibia, with or without an interposed graft. For men following a sedentary occupation, a pseudarthrosis permitting flexion has greater advantages. Either of them is better than an artificial leg. No operation should be done for pseudarthrosis until the skin wound is completely healed and the inflammation subsided. A number of further points for management of pseudarthrosis of elbow, etc., are given in minute detail. A combination of a metal plate screwed to the bone and a bone-periosteum graft has given very fine results in simple pseudarthrosis or when there is loss of substance in a limb with a single bone.

Wounds of the Foot: The integrity of the sole is extremely desirable, and reunion by primary intention particularly important here, even if certain bones have to be sacrificed to permit this. All operations on the anterior tarsus seem to give favorable results if there is no complication from the cicatrix or from the condition of the articulations. Vicious attitudes of the feet can be ameliorated by severing or transplanting tendons if the articulations are free. Partial resection of the calcaneum gives less unfavorable results if the foot is kept at a right angle throughout the treatment. On the whole, operations on the posterior tarsus often cause graver functional disturbance than disarticulation or a Syme amputation. Depage stated that in case of suppuration of the articulations of the tarsus, persisting in spite of astragalectomy, the suppuration can be conquered by severing tendons and ligaments enough to turn the foot forward or inward (*renversement du pied en avant ou en dedans*), keeping it with a bandage in this position, thus favoring disinfection of the focus. The foot can be restored to normal position in one or two weeks.

Osteosynthesis for Fractures: Primary osteosynthesis is a difficult operation which exposes to grave complications. It should be reserved for specialist skill. Apparatus give such good results now that it is rarely called for outside of pseudarthrosis cases. Temporary osteosynthesis with plate and screws is preferred.

75. Pernicious Anemia Plus Lymphadenosis.—The previously healthy soldier developed progressive pernicious anemia which kept up for months and then passed into lymphatic leukemia which soon proved fatal, with lymphadenosis. It had evidently been a case of leukemia from the start, the pernicious anemia findings being its earliest manifestation. Until the necropsy revealed the typical findings of lymphatic leukemia, the lymphadenosis seemed to have been merely superposed on a progressive pernicious anemia.

78. Medical Cure of Aneurysm.—Castellano's patient was a man of 50 who for a year had been having pain in the middle portion of the right supraclavicular region. Then he noticed a tumor, which rapidly increased in size and proved to be an enormous aneurysm of the trunk of the brachiocephalic artery. The man was kept absolutely quiet in bed, on a milk-vegetable diet, without much liquid, and he was given once a week a subcutaneous injection in the flank of 60 or 40 c.c. of a 2 per cent. solution of gelatinized serum. As the Wassermann reaction was positive, mercurial treatment was given at the same time. Improvement was rapid and pronounced. The only reaction to the injections was local pain, slight rise in temperature and transient leukocytosis. The aneurysm subsided to a clinical cure. The absolute repose in the horizontal position seemed to be an important element in the treatment. Twenty injections were made in this case.

82 *Pathology of Skin and I[illegible]logy. D. E. de Oyarzabal.—p. 193.

82. **Relations Between the Pathology of the Skin and Internal Pathology.**—De Oyarzabal discusses here the connection between liver disease and the color of the skin. His clinical observation has confirmed the existence of jaundice in certain cases when the liver seemed to be normal. The jaundice was evidently due to destruction of blood corpuscles and release of their pigment, but he thinks there is much evidence that it requires passage through the liver before it can induce jaundice. The amount of bile formed in the liver increases with the supply of the substances out of which the liver produces the bile. The pressure in the bile is normally less than the blood pressure, but if circumstances conspire to increase the bile pressure above that of the blood, then the bile passes into the blood. These data sustain the contention of Naunyn and others that there is no directly hematogenous jaundice; it is always the result of reabsorption. When the liver becomes atrophied and the circulation through it impeded, ascites develops unless the collateral circulation is sufficiently developed. A network of varicose veins over the region is a favorable sign, as this testifies to ample collateral circulation. We should aim to induce it and increase it; this is accomplished by tapping the ascites. This relieves the veins from the compression by the ascitic fluid, and the veins then dilate and assume the task of the collateral circulation. In regard to xanthoma and xanthelasma, he says that the connection between them and jaundice is not very clear or close. The frequency of jaundice and the rarity of the others, and the existence of xanthoma with apparently normal liver, seem to testify against such connection. On the other hand, cholesterol crystals have been found in xanthomas.

87 Mutations of Tubercle Bacilli. M. R. Castroman.—p. 140.

83. **Prophylaxis of Plague.**—Valdes is chief of the public health service at Rosario, and gives the regulations enforced there. A squadron is entrusted with the business of free deratization and disinfection of premises where plague is found, and no building can be erected or remodeled without an isolating cement floor, at least 5 c.c. thick, in the basement. These measures are enforced for warehouses and shops as well as dwellings. Some rats examined for plague were found with echinococcus cysts or streptothrix tumors.

84. **Crystals in the Blood as Determining Date of Death.**—Valverde reproduces thirteen microphotographs showing the varying aspect as time passes of certain characteristic crystals found in blood after death. These crystals are fragile and colorless; and their size is proportional to the interval since death, up to thirty-five days, and then they disappear. They are dissolved by acids but are not modified by bases or alcohol, and do not dissolve in water. They turn black under a 5 per cent. solution of silver nitrate, and blue under potassium ferrocyanid. These crystals are always found in putrefying blood, and sometimes even in aseptic blood. They appear the third or fourth day or even earlier in summer, the fifth or sixth day in winter. Their disappearance by the thirty-fifth day aids in determining the date of death. The crystals were found the fourth day in blood drawn from a living person, but a dried spot from a drop of his blood did not show the crystals till the fifteenth day. They have straight sides but coffin-like ends, and increase in size from less than one twelfth to over half the diameter of the microscopic field.

92 *Stones in the Ureters. P. *Martin.—p.* 124.

91. **Postconception Syphilis.**—Villapadierna says that if the child shows no signs of syphilis while the mother gives a positive Wassermann reaction, the question whether the child should be given to the mother to nurse should be decided only after serious consideration of the case. Several cases are described which show that the probability is that the new-born child is infected, even though it may show no signs of syphilis, even at necropsy.

92. **Concretions in the Ureter.**—Martin reports three cases, in a girl of 9, a boy of 11, and an adult. The diagnosis was made with the roentgen rays or cystoscope, and as the stones were small, they were dislodged and expelled by promoting the diuresis. He insists that morphin not only relieves the pain from an impacted stone but aids directly in its expulsion, as it relaxes the spasmodic contraction which is increasing the pain, and the increased pain induces greater contraction. Morphin breaks up this vicious circle, and as the spasm relaxes the stone drops down.

95 Necessity for Propaganda for Cremation C. Hoyos.—p. 140.
96 Prophylaxis of Venereal Disease. J. E. L. Silvero.—p. 142; R. B. Agramonte.—p. 143.

93. **Duodenal Alimentation in Treatment of Gastric Ulcer.**—Pages and Ibañez relate that this method has proved extremely successful in their hands. They describe here four typical cases in detail out of their total seventy-two cases in two years. They introduce the tube into the duodenum at night and feed with 150 gm. of tepid milk daily, then 200 gm., but never up to 300 gm., as this amount cannot be borne with comfort. Yolks of eggs are given, up to four a day. A saline injection is given after each feeding. The relief of pain is the first effect noted. The success was complete in all but two cases, one complicated with stenosis of the pylorus and one with actual and severe Reichmann's disease. With inoperable gastric cancer, some of the patients were relieved of pain and the general health improved under the duodenal feeding, but in others it not only failed to relieve but brought on gastric hemorrhage, sometimes fatal.

94. **Oxygen Treatment of Stomach Disease.**—By means of a stomach tube and generator, the stomach walls are treated with oxygen, and in the forty-eight cases reported the pain, hypersecretion and pylorospasm all subsided. The beneficial effects are most plainly evident in cases of long standing stomach disease, rebellious to the ordinary measures. In four of their cases the stomach symptoms had returned after a gastro-enterostomy, but were banished anew by the oxygen treatment.

106 War Wounds of the Eyes. R. A. Kats.—p. 606. Conclusion.

97. **Surgical Shock.**—Kruglevsky reviews what has been published on this subject by Crile, Seelig and Lyon, McNee and others, and endorses the general view that surgical shock is a complex process. The various phases of it include the increased ventilation of the lungs—hyperpnea, entailed by irritation of the respiratory center—and the reduced tension of carbon dioxid in the arterial blood—acapnia. The acapnia entails arrest of the respiration—apnea, which lasts until

normal CO_2 tension is restored. In case of very great losses by way of the increased ventilation of the lungs, the reserves of oxygen may be exhausted, and this entails death of vital organs. The insufficiency of O_2 entailed by apnea in each case induces a certain asphyxia of the tissues, accompanied by formation of nonvolatile acids—acidosis. The acidosis of the blood and tissues deranges the venopressor mechanism, in consequence of which filtration, diffusion and osmosis, exceeding the limits of physiologic functioning, draw out from the blood the greater part of its plasma, thus inducing acute oligemia and stagnation of the blood corpuscles in the small arteries. Thus death in all the aspects of surgical shock occurs with the manifestations characteristic of shock from hemorrhage.

The best means to ward off shock is by inhalation of O; for this he prefers Volhardt's technic. Injection directly into the blood of physiologic salt solution is useless in shock because this solution is unable to restore the osmotic tension in the blood and tissues, and hence does not diminish the stasis. Injection into the blood of a hypertonic solution of cooking salt reduces the extravasation of the plasma, but it has to be done in time. He adds that excision of the group of muscles involved is the best means for warding off shock from gas gangrene.

98. **Diaphragmatic Hernia from War Wound.**—Hagen-Torn concludes from his own experience and analysis of the literature that the possibility of rupture of the diaphragm and development of a hernia through it should always be borne in mind with a firearm wound in this region. It must not be forgotten that the clinical picture of diaphragmatic hernia refers to extreme cases, with protrusion of the stomach into the pleural cavity. In the majority of cases, however, with firearm wounds there is not enough of an opening for this; only the omentum and with it a loop of small intestine, slide into the chest cavity. The signs and symptoms from this form of hernia are less distinct, and they can be detected only by repeated careful examination of the patient. The roentgen rays are of great assistance in the differential diagnosis in certain conditions. A laparotomy besides the thoracotomy is required in some cases. He reiterates in conclusion that in perfecting the measures for differentiation of and for operating on diaphragmatic hernia, we must not forget that operative measures should be applied at once, without waiting for the appearance of signs of strangulation of stomach or bowel. He gives some roentgenograms taken with the patient lying prone and in others reclining on his back; the changes in the shadow with change of position are instructive. Grosser in 1899 had compiled 433 cases of diaphragmatic hernia, but most of them were found only at necropsy. Among those diagnosed during life, in nearly all the stomach was included in the hernia. No case is on record like the one Hagen-Torn reports in detail in which merely the omentum and a loop of small intestine formed the contents of the hernia, diagnosed before the operation. The patients do not complain of severe symptoms, the traction on the omentum, etc., being comparatively slight. The strangulation of the loop of small intestine may occur at a point where the bowel is comparatively less sensitive. These factors were combined in his case, so that he long hesitated before operating. Only his tenacious desire to get at the explanation of the cause of the vague pains experienced by the patient led to repeated examination and final correct interpretation of the findings, and successful operation.

104. **The Ferments in Infectious Diseases.**—Solovtzova here concludes her extensive study of the ferments in various infectious diseases, and especially their connection with the crisis. A number of diagrams and tables are given for comparison of the findings in respect to proteose, amino-acids, lipase and the protein split products, according to Sørensen, in the urine in relapsing fever. They show that as the temperature falls at the crisis, in relapsing fever, the proportion of proteolytic ferments is increased as a rule. The amount of the split products is reduced. The artificial crisis induced by intravenous introduction of drugs forms the exception to the rule, as with this the split products accumulate in the blood. The amount of amino-acids in the urine gradually increases, beginning with the attack and through to the falling temperature of the crisis; at the time of the crisis itself it jumps suddenly still higher. With the artificial crisis, this sudden upward jump is delayed and does not occur till the day after the crisis. Negative findings, or the absence of proteose, is observed only with a very severe crisis or unfavorable termination of the disease. Leukocytosis is observed at the crisis, but she found no morphologic changes in the blood. The findings with lipase are conflicting; generally it increases toward the crisis. Antitrypsin shows a reduction with the natural crisis and a rise with the artificial. The fall of the temperature at the crisis, she declares, is dependent on the massive appearance of the split products in the blood. With relapsing fever the drop in temperature at the crisis is dependent on the massive destruction of the spirochetes and—in all probability—on the disintegration of their bodies by the ferments of the organism. The ferments (toxins) generated by the spirochetes of relapsing fever evidently have little affinity for the cells of the organism. The most important cause of the favorable or unfavorable course and issue of infectious disease in human beings is the condition of and the relations between the ferments of the organism and the degree of affinity between them and the infecting agent.

She has previously published a similar study of the ferments in typhoid fever, and on the influence on the temperature of parenteral injection of albumin. She compares here her results with those of Vaughan, Joblin, Petersen and others, as published in The Journal and the *Journal of Experimental Medicine*.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

107 *Epidemic Meningitis. G. Kapsenberg.—p. 669.
108 *Albuminuria in Schoolchildren. J. M. Hamelberg.—p. 679.
109 Present Status of Asthma. S. Brandes.—p. 686.

107. **Contagiousness of Meningitis.**—Kapsenberg remarks that the meningococci are not restricted to the meninges but invade the nasopharynx which is open to the outer world, and thus every person with the disease is likely to spread the infection even after recovery. In the first week of the disease the cocci are found in the nasopharynx in from 54 to 78 per cent. of cases. But as the sick stay in the house and as there may not be susceptible persons in their immediate environment, other cases seldom develop directly from them. But the persons in the environment harbor the cocci, and as these healthy carriers go in and out they are liable to encounter some susceptible persons among the large numbers they meet, and the disease develops in these susceptible contacts. He cites various data along these lines, especially reports by Ostermann in 1906, among others, showing 70 per cent. of carriers found in the contacts; Bruns, 36.7 per cent. in 609 examined; and 10 per cent. in Kapsenberg's own experience last year among forty-one examined. It is possible that repeated reciprocal infection of each other by the sound carriers may induce conditions in one or more of them so that they finally acquire susceptibility, and thus develop the disease after having been merely a healthy carrier for some time. He emphasizes the necessity for seeking out all the carriers in the environment. When possible, they should be isolated. As a rule, their carriership is transient. But in any event they should be warned of their danger for others, and instructed how to reduce this danger to the minimum by controlling their sneezing, coughing, the use of the handkerchief, and other opportunities for droplet infection of others. But the vital thing is to detect the persons who are permanent carriers. They are the main source for the perpetuation of the disease, and if they can be discovered and rendered harmless, a great stride will have been made toward conquering the disease.

108. **Albuminuria in Schoolchildren.**—Hamelberg found albuminuria in nine of sixteen boys after a class in gymnastics while there was no albumin to be found in their urine on a day when there was no gymnastic class. This led to examination of the urine of 401 boys and 311 girls in the school. The examinations were made before and after the gymnas-

class and, when albuminuria was found, the child was ordered to bring morning urine for examination. The children were all of the upper grades in the school. Albuminuria before the gymnastics was evident in 8 per cent. of the boys and 24 per cent. of the girls; after gymnastics, in 14 per cent. of the boys and 33 per cent. of the girls. In both categories the percentages grew higher the older the children; among the girls of the sixth grade and higher grades the proportion was 49 per cent. This albuminuria of adolescents is generally extrarenal, and Hamelberg applied the postural test to all the children with albuminuria to decide to what extent lordosis was a factor. He had the children stand ten minutes in the military attention position, or kneel for ten minutes with the trunk held straight, or lie prone on the ground and lift themselves up by their hands on a bench placed close to them. This last exercise induces extreme lordosis and showed albuminuria in fourteen of thirty-four children who had given negative findings with the two other tests.

He remarks parenthetically that it took skilful suggestion sometimes to get the children to void urine repeatedly at such short intervals, but he accomplished it. The trunk of the child was always bare during these exercises; this enabled oversight not only of the lordosis but of the general nourishment, etc. The findings as a rule confirmed Jehle's statements that the lordosis which induces albuminuria is exclusively that in the upper portion of the lumbar spine, but Hamelberg does not agree with him that lordosis in this region is the sole explanation of albuminuria in children. Chemical tests show a difference in the albumin found in different cases. Fatigue is evidently a factor in some cases. To exclude fatigue, he had some gymnastic exercises done with the arms alone as the children lay on the floor. He draws no practical conclusions from this research except that the children who present this extrarenal albuminuria are the very ones who most need gymnastics and other measures to strengthen them. Fully 90 per cent. were frail children among those with lordotic albuminuria, and 70 per cent. of those with albuminuria in general; only 10 per cent. of the total were lively healthy children.

Hospitalstidende, Copenhagen

March 13, 1918, **61**, No. 11

110 *Fracture of Calcaneum. T. Eiken.—p. 321.
111 *Tests for Sugar Content of Blood. W. Leschly.—p. 326.
112 Present Status of Five-Day Fever. O. Thomsen.—p. 332.

110. **Isolated Fracture of Anterior Process of the Calcaneum.**—Eiken's patient was a young woman who twisted her foot in dancing; as she remembered, it was in supination. The foot was treated with bed rest and massage, but did not improve. She applied for treatment to five or six different physicians, and each treated her for the assumed sprain, or tendon or nervous trouble. She was up and about and even took part in dancing, but there was always pain in the foot, gradually increasing. Finally roentgenoscopy revealed the cause of the disturbances in an isolated fracture of the anterior process of the calcaneum at the point where there had been tenderness. There had been no swelling, according to her testimony, at any time. The foot could be moved freely except that rotating movements increased the pain, which then spread upward along the Achilles tendon. The fracture seemed to involve both the anterior articulation and the calcaneocuboid. A plaster cast was applied, with the foot at a right angle, for twenty days, with elevation for six. Roentgenoscopy showed considerable callus in three weeks. Crutches were then allowed and in four days the patient was walking with a cane, and there was only slight pain in walking and no tenderness except along the flexion tendon. This rapidly subsided and the girl was soon playing tennis and dancing. This is Eiken's fourth case of this fracture, but is the only one in which the fracture must have occurred from traction by the ligament. The fact that there was no dislocation of the fragment explains the comparatively slight disturbances. The case emphasizes the importance of early roentgen examination in all cases of severe sprains, even when no sign of fracture can be detected otherwise, especially when the injury occurred along the longitudinal axis. The continued use of the foot in this case kept the fracture from consolidating, and serious disturbance might have resulted as after two months of this there were no signs of healing. Hence the prompt healing under rest in a cast for twenty days was particularly striking.

111. **Comparative Determination of Sugar Content of Blood.**—Leschly applied to forty persons parallel tests with the Myers and Bailey technic and Bang's uranyl method for determination of the sugar in the blood. The results are tabulated with other metabolic findings. Only slight differences were found with the two technics. As the American method gives the sugar content in 100 c.c. of blood and Bang's in 100 gm. of blood, this is equivalent to the latter giving constantly 5 per cent. higher values than the former. As the solutions used in the Myers-Bailey keep well, this seems to be, he says, the preferable method when the test is to be made only occasionally. He adds that Bang's uranyl method is an improvement over his original technic, as this removes the iodin-binding substances. Leschly's research confirms that from 0.100 to 0.105 is the normal sugar range in the blood.

Hygiea, Stockholm

113 *Nasal Reflex Neuroses. A. Hofvendahl.—p. 321.
114 Glioma in Optic Nerve of Child. E. Rietz.—p. 344.
115 Cystosarcoma of the Mamma. H. Westermark.—p. 352.

113. **Nasal Reflex Neuroses.**—Hofvendahl says that experimental research has apparently shown that drugs and gland extracts which increase the tonus in the sympathetic nervous system modify the blood picture in the direction of neutrophils aneosinophilia, while those that increase the tonus in the cranial and sacral autonomic nerves (which may be designated as the parasympathetic system. It includes more than the vagus), modify the blood picture in the direction of mononuclears eosinophilia. The parasympathetic nerves in whatever organ they are found respond always alike with paralysis to atropin and with stimulation under pilocarpin. The sympathetic system, on the other hand, is not influenced by these but responds promptly to epinephrin and cholin. Hormones from the ductless glands and bacterial toxins are liable to induce similar contradictory effects on the sympathetic and the parasympathetic systems. Bronchial asthma is usually preceded by a copious watery discharge from the nose (overstimulation of the parasympathetic system) and swelling of the interior of the nose (irritation of the vasodilators which belong to this system), while the transient improvement under atropin testifies that this parasympathetic system is temporarily paralyzed by this drug. In three of eleven typical cases of nasal asthma, tuberculous toxins were evidently responsible for the irritation of the parasympathetic system and eosinophilia. This nasal neurosis sometimes long precedes other appreciable manifestations of tuberculosis. Hofvendahl found vasomotor disturbances in the nose in 10 per cent. of 500 tuberculous persons in the first and second stages of the disease. Thorough examination of the whole body is indispensable in cases of nasal neuroses. The sympathetic parasympathetic balance in such persons is easily upset, and this may occur from emotional stress, bacterial toxins, mechanical pressure, odors, pollen dust, etc. There is liable also to be an unstable balance in the endocrine system in such persons, especially the balance between the thyroid and genital glands, with a special tendency to disturbances during transitional periods. The slightest anomalies in the interior of the nose should be corrected in persons with this exaggerated reflex irritability of the nasal mucosa. In several of the cases reported, after removal of a polyp, the tendency to attacks of asthma progressively declined. In one case the nasal asthma first developed under a course of digitalis treatment and it subsided under atropin. Toxic action from the digitalis seems to have been responsible for the nasal reflex neurosis in this case. In one woman of 27 with bronchial asthma and symptoms of hyperthyroidism, they became much exaggerated with the onset of the menses. She sweated profusely during the attacks of asthma. There has been no return of the asthma since resection of a spine and crest which were much enlarged.

USE OF CORN (MAIZE) AS HUMAN FOOD

H. C. SHERMAN, Ph.D.
Professor of Food Chemistry, Columbia University
NEW YORK

About three fourths of the world's corn crop is produced and consumed in the United States, but considerably less than one tenth of it is used as human food. We produce three times as much corn as wheat, so that only one sixth of the corn crop need be eaten in order to replace, or save, one half of the wheat crop. In fact, the increase of our 1917 corn crop over the three-year average of the period from 1911 to 1913 is 548,000,000 bushels, or the equivalent of three fourths of a normal wheat crop. This extra corn is not needed for animal feeding, since the number of animals has not increased correspondingly. Much anxiety has been felt on account of the large proportion of soft corn, not suitable for grinding, in the 1917 crop; but this and much more will be fed to farm animals in any case. A fifth of the total corn crop or a third of what is suitable for milling, would, if consumed as human food, set free all the wheat needed for our friends abroad and leave enough corn on the farms for the adequate feeding of all the live stock now on hand.

In response to the appeals of the Food Administration, much has already been done by our people in the direction of wheat saving, either by direct diminution of bread-stuffs consumed or by substitution of other grains for a part of the wheat formerly used in bread-making. Of the various grains available as wheat substitutes, corn is so much the most important quantitatively that it has seemed well to study by carefully controlled experiments the value of corn as human food and the practicability of making it a large factor in the diet even of people previously accustomed to only a small and occasional use of corn products.

In a series of experiments on healthy men and women, carried out by the department of food chemistry, Columbia University, in cooperation with the New York Association for Improving the Condition of the Poor, special attention has been paid to the question of digestibility and to the nutritive value of the corn proteins. Four experiments were made on as many different subjects, one man and three women, none of whom had been accustomed to any considerable use of corn as food.

The man who served as subject for the first experiment was engaged primarily in studying the value of a simple mixed diet consisting very largely of wheat bread. As much as 600 gm., or more than 21 ounces, of bread were consumed daily with only small amounts of other foods. When the attempt was made at once to replace one third of this bread by an equivalent amount of corn meal, and to consume the latter in the form of mush, it was found that the quantity of mush was too large for the unaccustomed digestive tract already somewhat taxed by the large bulk of bread in the diet. The large quantity of mush was unpalatable and digestive discomfort was experienced. The nitrogen balance was difficult of interpretation because the total intake was diminished; but since the output was diminished to at least an equal extent, it appeared that the corn meal protein was as well utilized by the tissues as was an equal amount of protein from wheat flour.

In the second experiment, a woman, weighing from 59 to 60 kg. (from 130 to 132 pounds) studied the efficiency of wheat and corn proteins by making them prominent in a low-protein diet and determining the intake and output of nitrogen for twenty-three days. The protein intake was kept under 50 gm. per day and was distributed as follows: milk protein, 18 per cent.; wheat protein, 47 per cent.; corn protein, 31 per cent. This involved the consumption of nearly a half-pound of corn meal daily, namely, 200 gm., of which 90 gm. per day were eaten as mush and 110 gm. were mixed with wheat flour and eaten as bread. The subject maintained her weight and general health and energy, working in the laboratory about ten hours per day, notwithstanding the hot summer weather. Twice during the month, however, she experienced digestive discomfort with a tendency to flatulence and slight diarrhea. This was during some of the hottest days of the summer, and it is a question whether the discomfort should be attributed to the corn meal or to the fact that the diet as a whole was too bulky and too starchy for the season. Notwithstanding the small protein intake, nitrogen equilibrium was maintained throughout, indicating a very satisfactory efficiency of both the wheat and the corn proteins.

The third subject consumed 110 gm. of corn meal per day for eight days, after being twenty days on a known diet consisting largely of bread made in part from patent and in part from whole wheat flour. Of the corn meal eaten daily, 85 gm. were substituted for entire wheat flour and used in bread, and 25 gm. were eaten as mush in place of 25 gm. of sugar. The net effect of these substitutions was to leave the protein content and energy value of the diet very nearly unchanged, and the nitrogen balance showed that the tissues made as good use of the corn protein as of the wheat protein which it replaced. The subject felt, however, that the abrupt introduction of about 4 ounces of corn meal per day, in place of more familiar foods, rendered the diet more difficult of digestion.

In all three of these cases, the experimental diets containing corn meal included also considerable amounts of wheat flour. So it is a question whether the slight disturbances or discomfort of digestion should be attributed primarily to the corn meal or rather to the continued use of a bulky and starchy diet, especially as all of these experiments were made in summer. Another question that arises is, whether the corn meal used in these experiments was cooked in such a way as to be digested to the best advantage.

A fourth experiment was therefore planned, in which the amount of corn meal used was still larger, but it was baked in the form of thin scones so that the starch was more uniformly heated than in the baking of ordinary loaves of bread, and was presumably somewhat more thoroughly cooked than when simply boiled with water to a mush. More than 10 ounces (300 gm.) of corn meal were eaten daily, the remainder of the diet consisting of limited amounts of milk, fruit, sugar and fat. The corn meal furnished about half of the calories and three fourths of the protein of the diet. It replaced the whole amount of breadstuffs and cereals ordinarily eaten. Under these conditions there was no disturbance whatever of either appetite or digestion, although the corn meal diet was taken continuously for a month. Determination of the nitrogen balance showed that the maize protein functioned with unexpectedly high efficiency, since the equilibrium was maintained throughout the month with an intake of only 36 gm. of protein per day, of which three fourths was maize protein. The body weight of the subject was practically constant at 56 kg. throughout the month of the experimental diet.

In the last experiment, the corn meal was cooked by being mixed with boiling water and a little fat and salt, and baked in portions three-eighths inch thick for about one hour at low oven temperature to insure thorough and uniform heating throughout. The finished product, while only golden brown on the surface, was well done and crisp to the center. The thorough mastication and admixture with saliva, which the crispness of this form of corn bread insures, is probably a factor of some importance in its digestibility.

It is evident that corn meal, suitably cooked, can be substituted for corresponding wheat products even to an extent equivalent to the whole of the usual consumption of wheat in the dietaries of those who live largely on bread, without detriment to the nutritive value of the diet. When conditions are unfavorable or the subject is particularly sensitive to a change of food, a considerable substitution of corn for wheat may give rise to some discomfort in digestion; but in the three cases here observed, the nutrition of the body tissues appeared to be as well maintained as when the digestive process was entirely regular. It is confidently believed that suitably cooked corn products can enter into the dietary, even of those not accustomed to their use, in large proportion without any effect whatever on digestion. Nor need the palatability of such a diet suffer when even greater quantities of corn products are introduced in varied forms:

Acting on my suggestion as to the feasibility of deriving half the calories of a mixed diet from corn, some of my friends have experimented from the housekeeper's standpoint, with results wholly successful in palatability, in conformity to conventional menus, and in attractiveness to the eye.

Miss Monroe and her colleagues[1] prepared a week's meals, in the total of which 50.5 per cent. of the calories were contributed by corn products. The results of the twenty-one meals served are summarized in the accompanying tabulation.

Corn-wheat yeast bread, with one part corn meal to three parts wheat flour, was served at all meals, when no other bread is mentioned in the table. Corn oil was used in the more highly seasoned, but not in the bland salad dressings. Corn syrup was not substituted for sugar in any case in which substitution would be perceptible either to the eye or to the palate. There was no suggestion of monotony as one looked over and tasted the twenty-one meals in succession, and each individual meal was such as to be highly acceptable to the housewife or culinary expert of conventional ideas and high standards of palatability — not merely to the "scientific enthusiast."[2]

MENUS FOR TWENTY-ONE MEALS

Day	Breakfast	Luncheon	Dinner
1st	Malaga grapes; popped corn with cream; samp spoon bread, orange honey; coffee	Cheese polenta, tomato sauce; buttered peas and carrots; spice cake; tea	Boiled tongue, spinach; creamed hulled corn; hot corn bread; jellied apples; pop corn laces; coffee
2d	Grapefruit; corn flakes and cream; fried corn mush; maple corn syrup; coffee	Corn and chicken soup, corn bread croutons; green peppers stuffed with hominy grits; corn relish, steamed corn bread; maple custard, pop corn drops; tea	Baked cod, sauce tartare; corn meal bouletets; deviled *corn*; watercress salad; corn tutti frutti; coffee
3rd	Stewed apricots; puffed corn, top milk; creamed corn on toast; coffee	Escalloped corn; cider *jelly salad, johnny* cake crisps; cottage pudding, chocolate sauce	Yakhuah, baked corn *croquettes, pear salad*; popped corn pudding; coffee
4th	Crisp cereal with bananas; creamed hominy with hard cooked egg; spider corn cake; coffee	Corn chowder, corn sticks; corn bread salad; corn meal rolls; chocolate; *cornstarch pudding*; tea	Southern chicken pie; pineapple and cheese salad; steamed corn meal pudding with fruit sauce; coffee
5th	Stewed prunes; corn meal mush, cream; creamed herring, browned hulled corn; corn-wheat bread toasted; coffee	Gnocchi di farina gialla; grapefruit and orange salad; Richmond corn muffins; cocoa; spice cookies	Escalloped corn and oysters; asparagus with butter sauce; cabbage and pimento salad; corn meal banana fritters; *fruit sauce*; coffee
6th	Sliced oranges; cornlet griddle cakes, maple corn syrup; coffee	Escalloped hominy and cheese; tomato jelly salad, corn-wheat bread sandwiches; corn *short cake* with peaches; tea	Round steak, Swiss; potatoes in half shell; corn a la southern; corn-wheat rolls; romaine with chiffonade dressing; cornstarch and prune molds; coffee
7th	Baked apple; codfish mush balls; samp with cream sauce; *corn muffins*; coffee	Cream of kornlet soup; cooked corn sticks; corn meal and samp waffles, maple corn syrup; chilled pineapple and orange; cake; tea	Roast chicken, cranberry sauce; candied sweet potatoes; corn oysters; Waldorf salad; corn crackers; cheese; coffee; *corn syrup mints*

In another case,[3] two women, who had had some professional training in food work, but whose duties were such as to preclude the spending of much time on either the planning of menus or the preparation of meals, found that under every-day household conditions and without the adoption or development of any unusual combinations, it was easily practicable to derive more than one third of the week's calories from the products of ordinary field corn. Corn meal, corn flakes, puffed corn, hominy, cornstarch, corn oil, and corn syrup were used. A liberal use of fresh fruits and vegetables was found very helpful to the palatability of the diet, especially on those days on which much corn meal was used. With the diet thus supplemented, it was found that a week's daily use of enough of the corn products to furnish over one third of the calories caused no loss of appetite, nor disturbance nor discomfort of digestion, and was entirely satisfactory to the two women and to the man of the family.

---

[1] Monroe, Guilford and Colman: Data to be published in full by the Bureau of Publications of Teachers College, Columbia University, New York.

[2] An enthusiast could easily have made the corn kernel contribute a considerably higher percentage of the total number of calories by more frequent substitution of glucose for sucrose and of corn oil for olive oil, and by the use of a higher percentage of corn meal in bread-making, thus making a product of less conventional texture but equal food value.

[3] Allen and Short: Results to be published.

Granted that corn products may be substituted for those of wheat to a large extent, or entirely, if desired, without detriment to the attractiveness and palatability of the diet or to the nutritional condition as studied in human subjects by determination of intake and output in quantitative experiments of as much as a month's duration, the question may still arise in some minds as to whether long continued use of corn would give results in every way as favorable as the corresponding use of wheat.

The investigations of McCollum, in which laboratory animals have been kept on restricted diets, often for a lifetime, and in several cases for more than one generation, seem well calculated to bring to light any differences in the more obscure factors of food value or in the general wholesomeness of the two grains, if any such differences exist. In recent summaries of the results of an extended experience with such experiments, McCollum has repeatedly stated that wheat and maize are very similar in their dietary properties. If this seems surprising in view of the well known inadequacy of zein when fed as the sole protein of the diet, it should be recalled that Osborne and Mendel, to whom our knowledge of the nature of this deficiency of zein is so largely due, have demonstrated also that the other important protein of corn, maize glutelin, is adequate to meet all protein requirements and maintain a normal rate of growth when fed as the sole protein of the diet. They have also shown that zein, while inadequate alone, may yet take the major part in meeting the protein requirements, either of maintenance or of growth, when it is supplemented by a much smaller amount of milk protein.

Persistent use of a diet consisting too exclusively of corn products may lead to unfavorable results, but this is true of the other grains as well. To quote a very recent article by McCollum: "When an animal is fed solely on a single kind of seed, regardless of the kind of plant from which it is derived, loss of weight ensues and death is certain to supervene." This is as true of wheat as of corn, and is no argument against the partial or complete substitution of the one for the other. To the slight extent that two such similar seeds may supplement each other, the substitution of corn for, say, half the wheat ordinarily eaten may improve the biologic value of a diet drawn largely from these grains. Seeds should, however, be supplemented not so much by other seeds as by leaves and tubers, and still better by milk. Quoting McCollum again: "Moderate amounts of milk supplement the deficiencies of the seeds most satisfactorily, and its use forms the greatest factor of safety in our diet."

It is probably no longer necessary to point out that, if pellagra is due to faulty diet, the fault lies not in the use of corn, but in the fact that the diet contains too little of foods of other types. Lusk[4] has recently stated the case of pellagra in the corn belt and the use of corn as food as follows:

> It must be here definitely stated that the use of corn meal is not the cause of pellagra, provided the right kind of other foods be taken with it. . . . Pellagra is generally believed to be produced by a too exclusive use of highly milled corn and wheat flour in association with salt meats and canned goods, all of which are deficient in vitamins. The administration of fresh milk is naturally indicated. Goldberger states that after the addition of milk to the diet of a pellagrin, the typical clinical picture of pellagra no longer persists. The poor in the mill towns of the South lived too exclusively on a corn diet without admixture of milk or fresh animal food or even of cabbage, and pellagra has been the consequence.
>
> The Food Administrator asks us to eat corn bread and save the wheat for export. It is a very small sacrifice to eat corn bread at one meal or more a day. Indian corn saved our New England ancestors from starvation, and we can in part substitute it for our wheat and send the latter abroad to spare others from starvation. The simplest elements of patriotism demand that we do this.

The plea for a fuller use of corn as human food in place of a part of the wheat which we ordinarily consume gains new emphasis and significance from the fact that the wheat situation is becoming constantly more acute, and all indications are that even with a good crop this summer, economy of wheat will continue to be a pressing problem for at least the coming year, whatever may be the fortunes of war.

SKIN GRAFTING*

J. C. MASSON, M.D.
ROCHESTER, MINN.

At no time in the world's history have there been under treatment so many persons injured and crippled as now. As a great majority of these are suffering from infected wounds, frequently with a great deal of sloughing and destruction of extensive areas of skin and superficial tissues, anything that will tend to hasten healing and cover raw surfaces will be a great benefit to the patient, and a great saving in time and money.

Much has been done in the way of simplifying dressings, and in the control of infection by the scientific application of time-honored surgical principles, and the introduction of antiseptics that have a maximum bactericidal action and a minimum destructive action on the tissues. I shall not, however, dwell on the treatment of wounds or on the major surgical operations indicated, but shall confine myself to the final stage of the treatment of most infected wounds, that is the covering of the raw surfaces with skin.

A great many wounds primarily infected are, under modern methods, made rapidly sterile, as shown by the disappearance of pus and bacteria, and may then be closed with impunity like any fresh wound. But in many of these cases, when there has been extensive destruction of skin, the healthy edges of the raw surfaces cannot be brought together by the ordinary plastic method, and skin grafting must be resorted to.

In reviewing the history of surgery it is not surprising to note that skin grafting was one of the first operations attempted; in fact, it is asserted that the ancient Hindus and Egyptians successfully transplanted skin before the Christian era, and it is generally accepted that this operation has been done with varying degrees of success in different parts of the world ever since. It was not, however, until 1869, following the reading of a paper and the presentation of a case by Reverdin before the Société de chirurgie in Paris, that it was accepted as a regular surgical procedure, and since that time a great deal has been written on the subject.

---

[4] Lusk, Graham: Scient. Month., 1917, 5, 298-309.

* From the Mayo Clinic.

* Presented before the Olmsted County Medical Association, Rochester, Minn., April 10, 1918.

The grafts, as first suggested by Reverdin, were very similar to those that we now accept as probably of the best type of graft for use in the ordinary case in which closure of the wound is the all important consideration. These are small island grafts, principally epidermic, but containing some dermis in the center, and called by Davis small, deep skin grafts. The other accepted and useful grafts are known as Thiersch grafts and Wolfe grafts. The former are thin sheets of skin, removed with a razor, and include all the layers of the epidermis and possibly a portion of the dermis; the latter are composed of the entire thickness of the skin, and when successfully used are the most satisfactory.

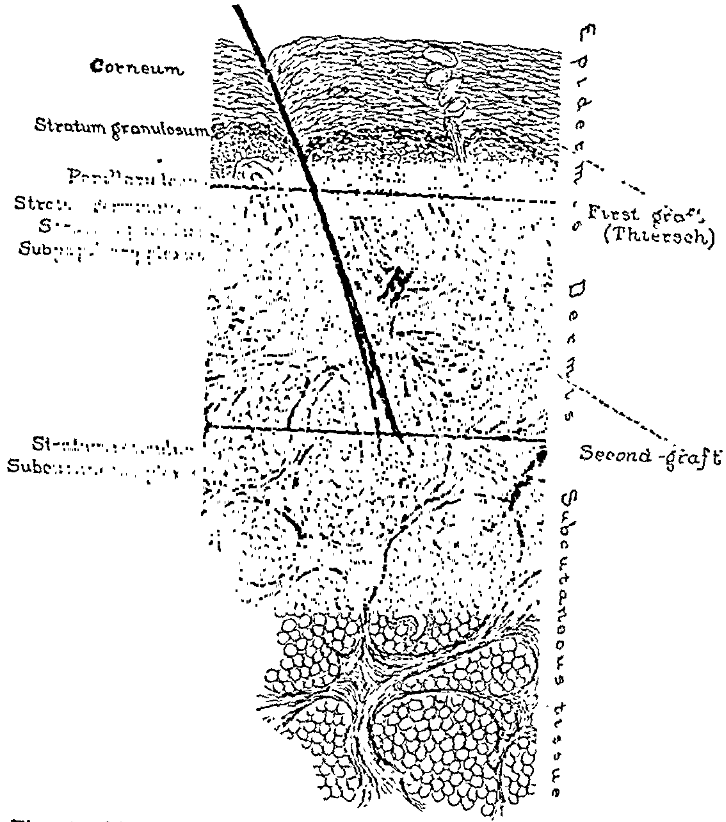

Fig. 1.—Normal skin, showing part utilized in Thiersch graft, and the deep part utilized by a new method.

Skin grafting is divided into three distinct types, depending entirely on where the grafts are obtained: (1) autoplastic grafts—skin taken from another part of the body of the patient; (2) isoplastic grafts—skin taken from another person, and (3) zooplastic grafts—skin taken from one of the lower animals. All authorities agree that the autograft is the most satisfactory, and a great many hesitate to use even isografts when it is possible to get skin from the patient.

I myself have had no experience in the use of zoodermic grafts, but am satisfied that there is a much larger field of usefulness for the isograft than is generally believed. When one takes into consideration the ease with which good grafting material may be obtained in the operating room without discomfort or inconvenience to the donor, and with the removal of all dread of the operation from the recipient, one is convinced that it should certainly be more frequently practiced. In isografting, the cause of failure should not always be attributed to the graft itself, since it may be due to the patient, to the condition of the wound or to the after-care and dressing, etc. This problem is especially difficult to solve in private practice, in which time is such an important consideration to the patient and little or no help can be obtained by experimental work.

In all the patients requiring skin grafting who were under my care during the past year, the blood of the donor, as well as that of the recipient, has been tested for agglutination. The results have been very interesting and instructive, and I feel sure will add a great deal to the popularity of the use of the isograft. In many cases the method will obviate the unnecessary removal of skin when there is little or no likelihood of its taking. I have tested the principle with the three varieties of grafts, and am satisfied that blood grouping is just as important for good results in skin grafting as it is necessary in transfusion, and that it is governed by the same principles.[1] While the results obtained are not positive, nevertheless, I have never had the skin take which was removed from a donor whose red blood corpuscles were agglutinated by the serum of the patient. The results in all other cases have been very satisfactory, almost, if not entirely, equal to autodermic grafting. In most cases in which a donor's skin is to be used, a Wassermann test should be made to guard against syphilitic infection.

In any case in which it is considered expedient to resort to skin grafting, the first consideration is to have the raw suface in a healthy condition. Experience shows that only poor results can be expected on an indolent ulcer, one covered with exuberant granulation tissue or one in which the microscopic slide shows numerous bacteria. Grafting may be satisfactorily done on fresh raw surfaces, but pedicle or plastic grafts are, as a rule, more satisfactory in these cases, and true skin grafting is much more frequently indicated as a secondary method in closing open wounds or ulcers.

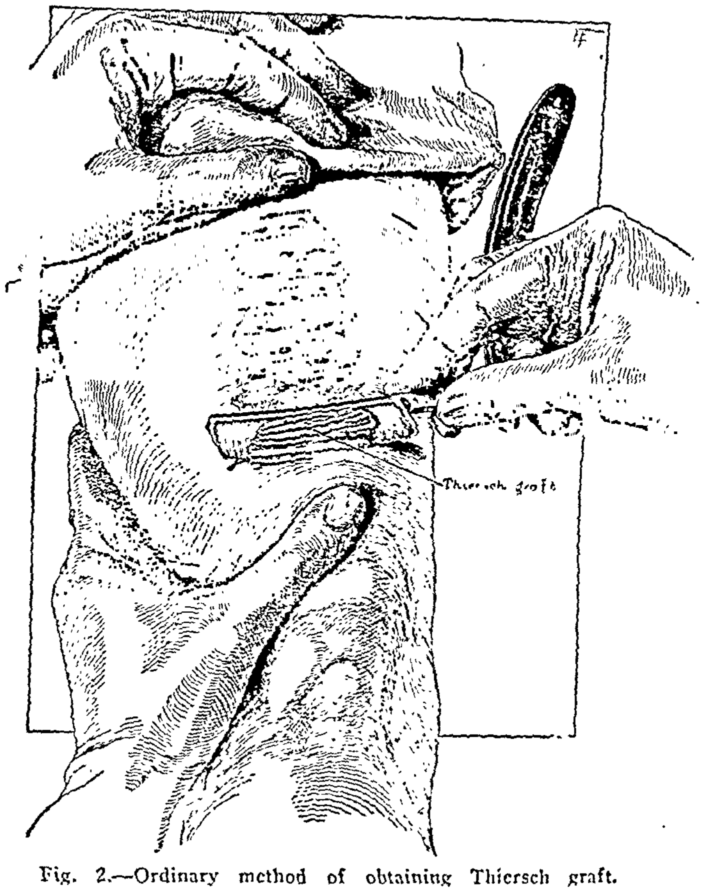

Fig. 2.—Ordinary method of obtaining Thiersch graft.

---

1. Sanford, A. H.: Selection of the Donor for Transfusion, Journal-Lancet, 1917, 37, 698.

In all chronic ulcers, especially those resulting from oentgen-ray or electric burns, the first consideration s to improve the circulation in the part, and to stimuate healing by the removal of the unhealthy granulaions, either by curetting or by excision of the ulcer. ;rafts may be placed immediately, but in most cases t is advisable to apply to the raw surface hot saline r boracic dressings until it is covered with healthy ranulations, and in some cases it is desirable to use carlet red ointment (8 per cent.) once in two days intil a healthy condition of the granulating surface s obtained and a small pellicle of new skin appears long the edge. Satisfactory results can then be xpected from grafting.

In the more recent cases, such as are so often seen n patients following burns, extensive superficial infecions, or radical operations in malignancy, the best lan is to apply hot saline, neutral solution of chlorinted soda (Dakin's solution) or lichloramin-T, until the wound is nade sterile, as shown by smears n three consecutive days. The rafts may then be applied direct, r, if the granulations are exuberant, they may first e curetted away or rubbed off with a piece of dry auze, controlling hemorrhage by pressure with gauze rung dry from hot saline solution and applying the rafts immediately, pressing them well into place with noist gauze. If there is much oozing it is better to lelay the placing of grafts for twenty-four hours, eeping up the hot moist dressings.

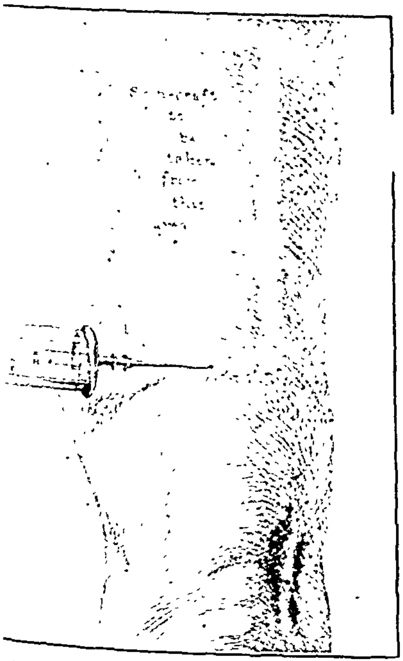

Fig. 3.—Superficial blocking with local aneshesia for skin grafting.

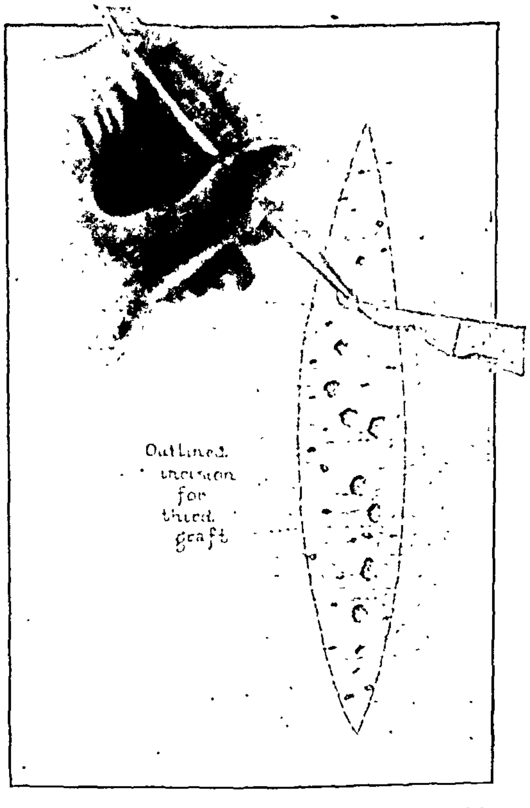

Fig. 4.—Further utilization of area from which Thiersch graft has been removed.

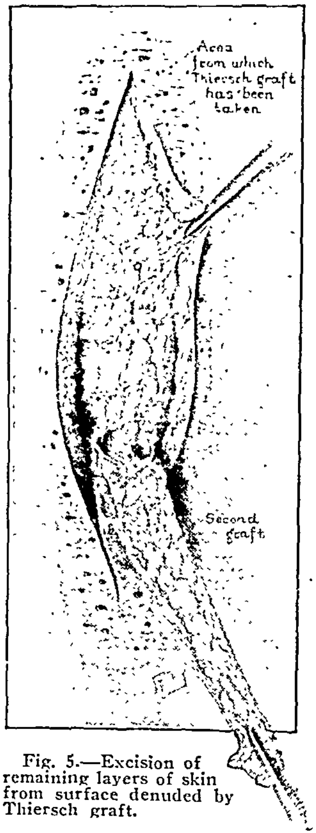

Fig. 5.—Excision of remaining layers of skin from surface denuded by Thiersch graft.

The types of grafts to be used and where they shall e obtained are very important considerations. The ull thickness, or Wolfe graft, gives the most normal ooking and best functionating skin, but has the disdvantage that it is not so apt to take as is either the Reverdin or Thiersch graft. However, in annular lcers of the extremities, around joints, or in dealing vith extensive areas, it is necessary to have at least part of the surface covered with grafts of the entire hickness of the skin.

In deciding where to obtain grafts, the type of skin desired should naturally be considered. For most cases the skin from the anterior and outer surface of the thigh or upper arm will be found best, whether it be from the patient himself or from a donor.

General anesthesia is frequently advisable, but even extensive grafts may be obtained under local anesthesia with very little discomfort to the donor, although so far as the operation or the surgeon is concerned, the latter has no advantage. It is much easier, however, to obtain a donor if it is understood that he will not be anesthetized.

It makes very little difference what method is used in preparing the skin, and the iodin method is as satisfactory as any. The area is first cleaned with benzin containing 1:1,000 iodin, and after drying, it is given two coats of 3.5 per cent. iodin in alcohol. Figure 1 is a transverse section of the normal skin. A Thiersch graft is then cut after the ordinary method (Fig. 2). If local anesthesia is to be used, the skin is injected as shown in Figure 3. If the skin is thick, a second layer may be removed from the same area in the same way, or small island grafts may be taken from the center of the raw surface to include some of the deeper layers of the epidermis and some of the superficial layers of the dermis (Fig. 4).

It is advisable to reduce the size of the wound, especially if much of the dermis has been removed, by cutting an elliptical piece of tissue (Fig. 5) and suturing the edges together with silkworm gut and horsehair. The tissue thus removed may be utilized for grafting by cutting it into small, [illegible] grafts (a term used by Colebrook and [illegible] applying just as the Reverdin grafts [illegible] Figure 6 shows the wound [illegible] grafts and small, deep grafts taken from [illegible] area. The advantages of this method are: (1) Grafting material equal to twice the denuded area is obtained; (2) it is easily and quickly done and is especially suited for local anesthesia, and (3) the clean cut wound may be expected to heal by primary union after being sutured with silkworm gut and horsehair, which has a distinct advantage over the raw area left after the Thiersch method or the necessary multiple wounds of the Reverdin method.

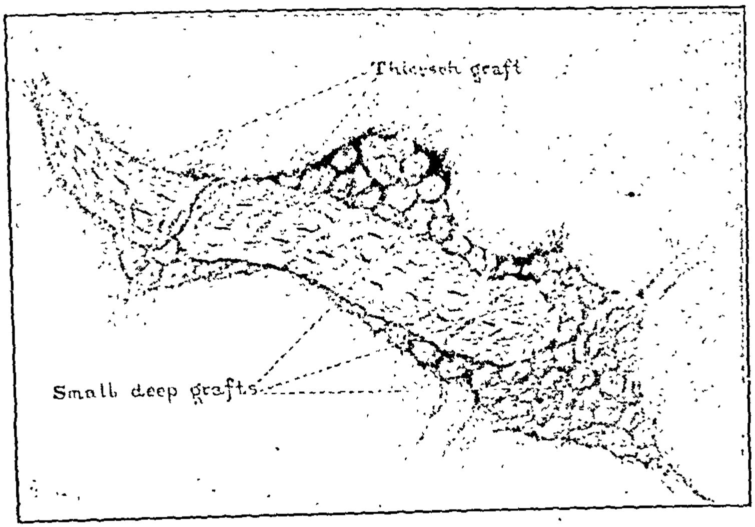

Fig. 6.—Wound covered with Thiersch grafts and small deep grafts taken from denuded area.

If large grafts, either Thiersch or those from superficial dermic layers, are used, they should be punctured at numerous points to allow the free escape of serum, which would otherwise tend to float them from the surface.

The type of dressing to use is of the utmost importance and varies with the nature of the case. If the wound is completely covered with Thiersch grafts, the open method of treatment, that of protecting the surface with a wire screen, is probably the best, with an occasional removal of any crusts or thick secretions and the application by atomizer of dichloramin-T (4 per cent.) or neutral solution of chlorinated soda. If the wound is only partially covered with grafts, the most satisfactory dressing is first to cover the raw surface and grafts with open-mesh net that has been previously impregnated with paraffin, and then to apply a wet dressing, which should be changed every four hours for three days without disturbing the paraffined net, the latter being held in place by sutures or by applying soft paraffin along the edges to fix it to the surrounding skin. Open air treatment is then combined with hot dressings, the hot dressings being used at night and the wound left exposed during the greater part of the day and sprayed once or twice during the twelve hours with neutral solution of chlorinated soda. As a rule, grafts have taken well in one week's time, after which sterile petrolatum makes a very satisfactory dressing.

Frequently the paraffined net becomes firmly adherent to the grafts while wet dressings are being combined with open air treatment; but it may easily be freed by applying a liberal petrolatum dressing or by spraying with liquid petrolatum for from four to six hours before attempting its removal.

Body Heat and Oxidation.—The total quantity of heat produced by the body is a measure of the intensity of the oxidation of carbohydrate, fat, and protein within the body.—Lusk, Food in War Time.

PHYSIOLOGIC COLECTOMY IN CHRONI TOXEMIAS OF INTESTINAL ORIGIN

CHARLES A. L. REED, M.D.

CINCINNATI

The cumulative experience of both physicians an surgeons engaged in a large way with the treatment o gastro-intestinal conditions, and of experimenta scientists in dealing with these problems, tends to confirm what may be expressed as at least tentative conclusions as follows:

1. The origin of certain toxins and of the no recognized anaphylatoxin[1]. demonstrated to be prese in certain toxemias, both convulsive and nonconvu sive in type, is due to certain conditions of stasis i the gastro-intestinal tract.

2. Stasis in the gastro-intestinal tract implies (a fecal retardation in either the small intestine or th colon or both; (*b*) venous retardation in either th mesocolic circulation or the mesenteric circulation c both, and (*c*) retardation in the lymphatic circulatic of both the mesocolon and the mesentery.

3. These three forms of stasis are associated wi and obviously dependent on some form of gastr intestinal displacement or other distortion, and ar therefore, primarily mechanical in origin.

4. There can be no permanent benefit from trea ment in these cases of stasis with consequent constit tional manifestations without first a correction of tl initial link in the chain of pathologic sequences ju enumerated. This can be accomplished in the majori of cases only by the surgical correction of the di placements or distortions of the gastro-intestinal tra as revealed by careful diagnostic methods, oft including exploratory incision.

It is of the highest importance that the gener practitioner who is the attendant in the first instan of these unfortunate persons should know just wh surgical measures are available for their relief, a just what results may reasonably be expected. In th connection it is important at the very outset to emph size the rule that either no surgery at all or the lea

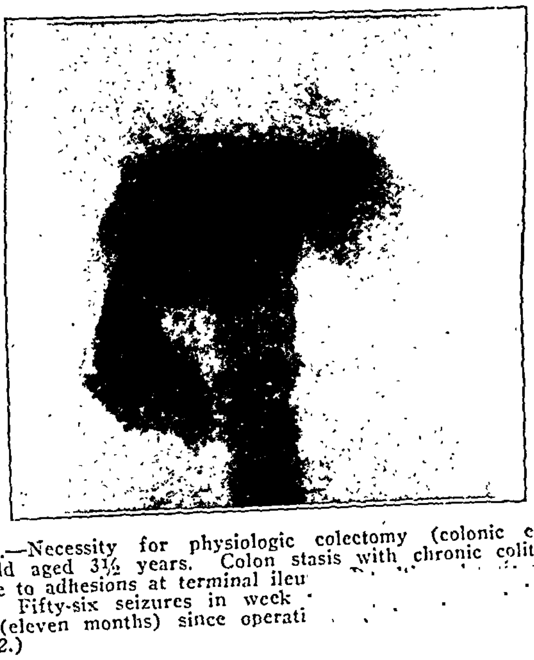

Fig. 1.—Necessity for physiologic colectomy (colonic exclusio in a child aged 3½ years. Colon stasis with chronic colitis. Il nvuls stasis due to adhesions at terminal ileu seiz toxemia. Fifty-six seizures in week sho to date (eleven months) since operati in Fig. 2.)

---

[1] Novy, F. G., and DeKruiff, P. H.: Anaphylatoxin and Anaphyla The Journal A. M. A., May 26, 1917, p. 1524.

and safest surgery possible should be employed to accomplish the end in view. My own practice under this rule began with the conservative nonsurgical treatment consisting of diet judiciously applied, visceral massage, posture and attempted mechanical support of the displaced and generally ptotic organs. This regimen was effective in producing even symptomatic cures in only a limited number of cases. I then devised the operation of parietal implantation of the colon with anchorage of the stomach.[2]

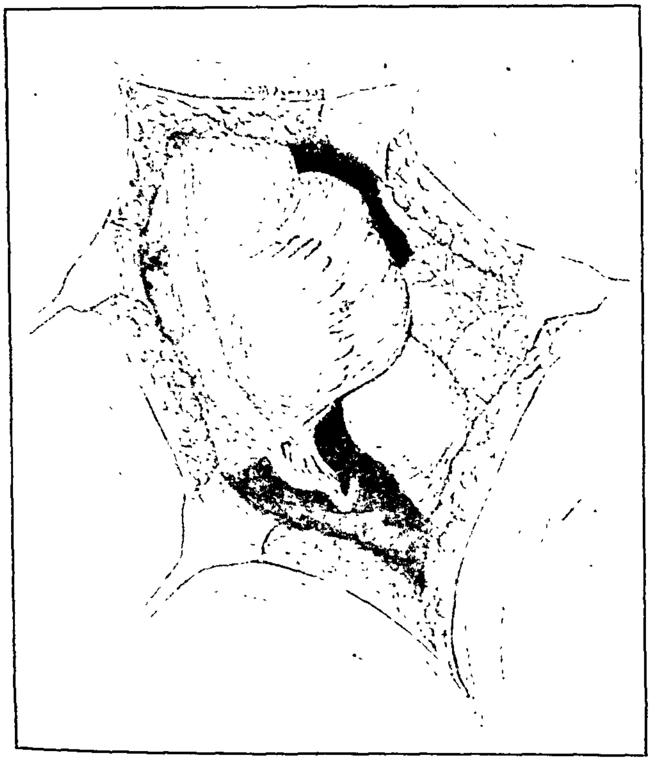

Fig. 2.—Stricture at ileocecal juncture with dilatation of the ileum and extensive exudate (Jackson membrane) over the cecum. (Same as Fig. 1).

I found this procedure not only primarily but permanently effective in a much larger percentage of cases. There were, however, certain cases, particularly of the chronic convulsive type, in which secondary changes in the colon seemed to preclude the possibility of functional restoration and consequently demanded its exclusion from functional duty. This led me to adopt Lane's procedure of ileosigmoidostomy. Satisfactory results were defeated in some but not all of these cases by anastaltic loading of the disused colon; but in some others in which this did not occur, follicular hypertrophy and hypersecretion of mucus associated with atrophy of the muscularis persisted and the toxigenesis continued. I then practiced colectomy with the result that I found it a prohibitively dangerous procedure, especially in chronic convulsive toxemias, and one justified only by extreme conditions in this or any other class of cases. In the instances in which complete relief from both local and constitutional symptoms followed removal of the large bowel, I became convinced that the salutary result was attributable in an important degree at least to the fact that retardative traction had thereby been removed from the superior mesenteric vein, and the venous turgescence of the mesocolic and mesenteric circulation had consequently been corrected. It will be seen, therefore, that the necessities of the situation demanded some procedure which would be less dangerous than primary colectomy. I therefore tried to do this operation at two stages, namely, a primary ileosigmoidostomy and secondary removal of the colon. In occasional instances, however, anastalsis was pronounced, with the result that the unused colon speedily became loaded, causing an aggravation rather than an amelioration of the toxemic phenomena. A secondary colectomy was thus made necessary before adequate benefit had been derived from the first stage of the operation. This experience forced on me a realization of the importance of devising some means against anastaltic loading of the colon following ileosigmoidostomy, with the result that I beg leave to report on the methods thus evolved.

Before doing so, however, I feel that it is important to call attention to certain modifications which I have adopted in the manner of doing ileosigmoidostomy. Thus it will have been noted that in practically all illustrations of ileosigmoidostomy there is either an end-to-side anastomosis or a side-to-side anastomosis with the proximal ileum coming down from above. In all cases that I have seen, the proximal ileum lies loosely on the floor of the pelvis, from which it comes up or may be brought up to the level of the sigmoid. It follows, therefore, that, to avoid retardative angulation at the point of anastomosis, the terminus of the proximal ileum should point upward rather than downward. End-to-side anastomosis between the ileum and sigmoid, whether done by the button or by suture, is sure to be followed by enough cicatricial contraction of the resulting stoma to interfere with free discharge of the ileac content. The use of the clamps in ileosigmoidostomy is both unnecessary and cumbersome, and interferes with the intelligent control of incidental hemorrhage. These considerations have prompted me to revise the technic as follows:

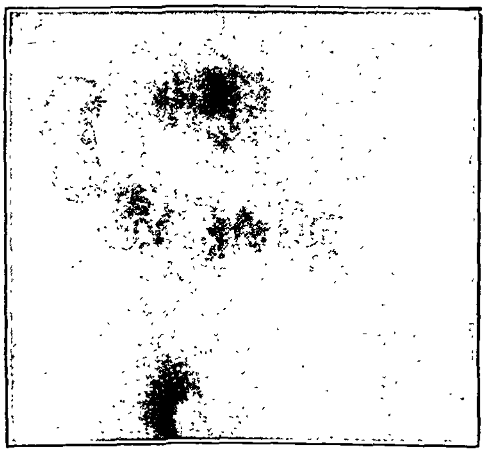

Fig. 3.—Stasis in remnant of transverse colon after right side colectomy, retardative angulation at splenic flexure not being relieved.

REVISED TECHNIC OF ILEOSIGMOIDOSTOMY

1. Approximate the ileum and sigmoid with walls relaxed for a distance of about 2½ inches, taking care that the ileum proximal to this point shall hang freely in the pelvis.

2. Stitch the ileum to the outside of one tenia of the sigmoid, using fine but strong Japanese silk for the purpose of carrying this suture line the full length of the pror anastomosis.

---

[2] Reed, C. A. L.: Fixation of the Ptosic Stomach and Colon by Retroperitoneal Implantation, The Journal A. M. A., March 28, 1914, p. 999.

3. Open both the ileum and the sigmoid nearly the full length of this suture line, controlling the always slight hemorrhage when necessary by forceps pressure.

4. Trim away the tissue from the free margin of the sigmoidal incision back to the other tenia and also cut away a very little tissue from the free margin of the ileac incision.

5. Suture the cut margins together with hemostatic stitch of small chromic gut, the suture line being frequently interrupted by a lock knot, tied without cutting the thread, the hemostatic suture being carried around to point of beginning.

6. The outer line of suture is then continued to the point of beginning.

7. The ileum is then clamped about three-quarters inch from the distal end of the anastomosis with two parallel hemostats and divided between, the cut edges of the intestine being treated with tincture of iodin.

8. The end of the proximal (anastomosed) ileum is then stitched over the hemostat and infolded, this process being supplemented by another infolding by a purse-string suture with the object of inverting the end of the ileum wedgelike into and through the upper end of the long anastomotic stoma. In this way the stoma is pried open and held open, thus obviating the use of the always difficult and sometimes mischievous tube. The problem of the "blind end" of the ileum is thus also eliminated.

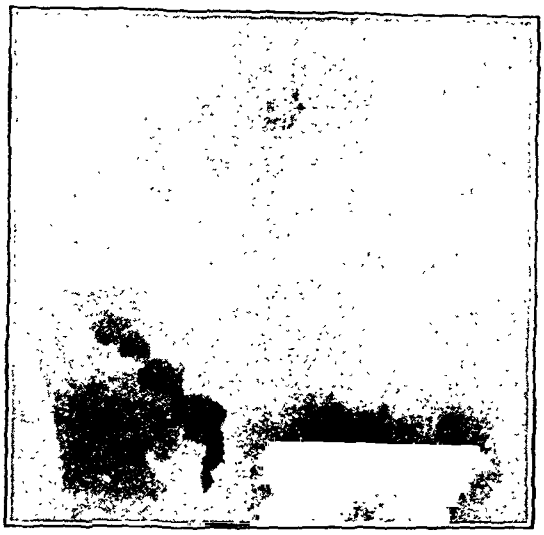

Fig. 4.—Ileac stasis after right side colectomy with end-to-side anastomosis, the retardation in the ileum being due to contraction of the anastomotic stoma.

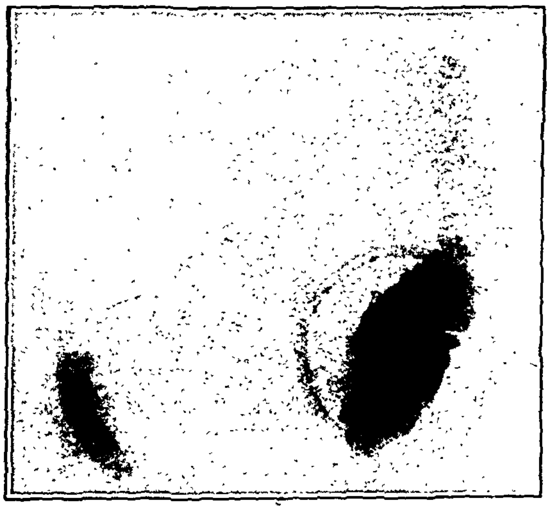

Fig. 5.—Complete relief of ileac stasis by parietal implantation of the colon and cecostomy. The cecostomy tube is shown in situ. Complete relief of toxemic symptoms.

PHYSIOLOGIC COLECTOMY WITH COMPLETE EXCLUSION OF THE LARGE BOWEL (FIG. 8)

The first method to evolve in my hands was based on the conception that, in doing a two-stage colectomy, the first stage — that of ileosigmoidostomy as just described — might be safely supplemented by complete exclusion of the colon, based on the experiments of Barbour to the effect that the disused colon rapidly undergoes atrophy both in its walls and in its follicular elements.[1]

1. Open the abdomen by a 6-inch oblique incision in the left lower quadrant.

2. Explore the abdomen and break up all adhesions, taking great care to isolate the terminal ileum at its cecal connection, which can generally be done by elevating the abdominal wall with a retractor.

3. Do an ileosigmoidostomy as described in the preceding paragraph.

4. Divide the sigmoid in its upper arch at a point from 2 to 4 inches above the anastomosis.

5. Close the upper end of the distal sigmoid by infolding with at least three layers of sutures, the last or peritoneal layer being of fine but strong silk.

6. Stitch the open end of the proximal sigmoid in the upper angle of the incision.

7. Stitch the open end of the distal ileum in the lower angle of the incision.

8. Close the intervening part of the incision with laminated chromic catgut fortified with two or three *en masse* silkworm sutures.

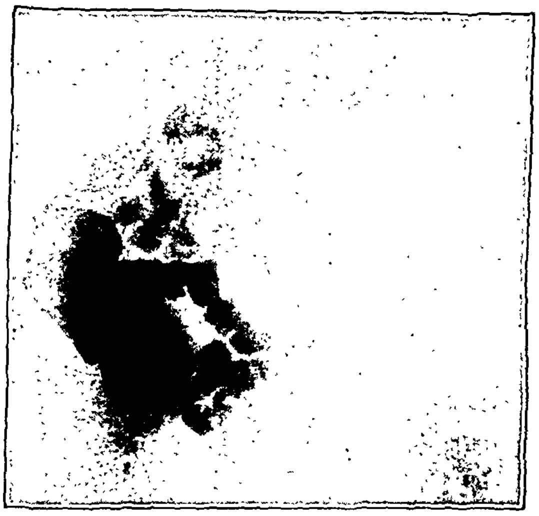

Fig. 6.—Failure to relieve ileac stasis by parietal implantation c the colon and cecostomy with resulting failure to relieve the constiti tional symptoms.

9. Insert a large size catheter through the open ileum int the cecum and a large tube (1.5 cm.) into the open orific of the proximal sigmoid.

10. Insert a rectal tube with several perforations up to bu not through the anastomosis.

The tubes should be left in position from a week tc ten days. Irrigations of the colon should be inaugurated on the third day and kept up daily until all feca discharge ceases. The tubes may then be removed and put back only as needed for irrigations. The intervals between irrigations may now be prolonged to two days according to the amount of mucus secreted. The secretion diminishes with the progressive atrophy of the disused bowel. In practically all of my cases it has become negligible in from six to ten weeks, the exceptions being those cases in which mucous colitis, always present in some degree, is unusually severe. In all instances the patients are speedily up and about their daily occupations following primary surgical recovery. Thus, for example, a schoolteacher has resumed her occupation, a bridge-builder is working on the channel span of a new structure, a lineman is climbing poles and working with live wires, a farmer is back at his crops, a stenographer is again at her desk, a mechanical engineer is again in charge of the power of a large establishment, a large manufacturer is again running his business, a child of 3½ is again at play. In none of these exacting occupations is the condition resulting from this form of colon exclusion proving to be an embarrassment, particularly as compared with conditions prevailing before the operation.

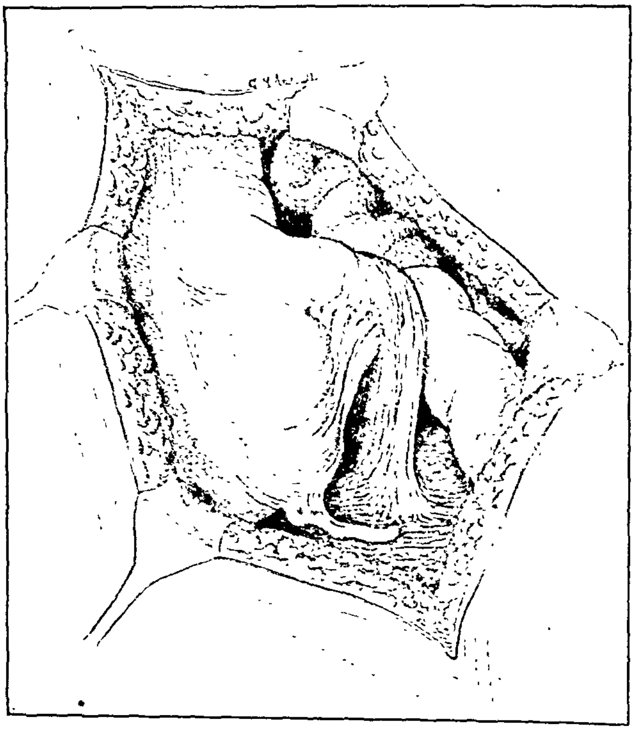

Fig. 7.—Extensive band adhesion at the terminal ileum causing marked ileac stasis with dilatation of small intestine.

The further argument in favor of this procedure as the first stage of a possible anatomic colectomy may be stated as follows:

1. It is less dangerous than a primary colectomy. In a series of thirty-one cases, I have lost only one due to the operation itself. In this case, the patient died in apparently anaphylactic shock from fecal extravasation into the peritoneum due to analstatic pressure on the occluded distal sigmoid. In the two other cases, lost in this series, one, a child, aged 3½ years, died on the eighth day in serial convulsions, while, in the other, a male adult, death resulted from anuria.

2. It facilitates detoxication of, first, the alimentary canal and, second, the general system.

3. It tends in most cases to arrest the toxigenic process and thus to restore the normal surgical resistance of the patient.

4. It so far restores the general health without establishing embarrassing local conditions that I have not so far had to do a single anatomic extirpation as a secondary procedure.

5. If secondary operation shall become necessary, this primary procedure will have caused detoxication of the patient with restoration of surgical resistance, while the atrophy of the colon with corresponding shrinkage of blood vessels and nerves will have materially diminished the technical difficulties of the final procedure.

The argument against this operation is as follows:

1. It is always associated with some superficial *B. coli* infection which, however, through the use of a solution of sodium para-toluenesulphochloramin (chlorazene), during and after operation, has never proved serious.

2. In at least 5 per cent. of the cases and in spite of all precautions, pressure from anastalsis is liable to force open the upper end of the sigmoid, thus necessitating a secondary operation for its closure.

3. In one case I have had a ventral hernia develop from the upper or colon end of the incision.

4. The two intestinal orifices, not troublesome but requiring some attention, are, however, permanent unless a secondary operation is done. This secondary operation may be (*a*) either a complete extirpation of the colon as I at first contemplated but have not yet had occasion to do, or (*b*) a restitution of the tract with formation of an intrasigmoidal valve such as I am about to describe.

PHYSIOLOGIC COLECTOMY WITH CIRCUAR INTRASIGMOIDAL VALVE (FIG. 9)

The objections to the operation of colonic exclusion as first described prompted me to devise a procedure against anastaltic pressure, one that would require less attention and would less likely require secondary operation for its termination. The result was the procedure which is done as follows:

1. Make the ileosigmoidostomy by side-to-side anastomosis, as already described in this paper.

2. Divide the upper arch of the sigmoid, if possible, 4 inches above the anastomosis.

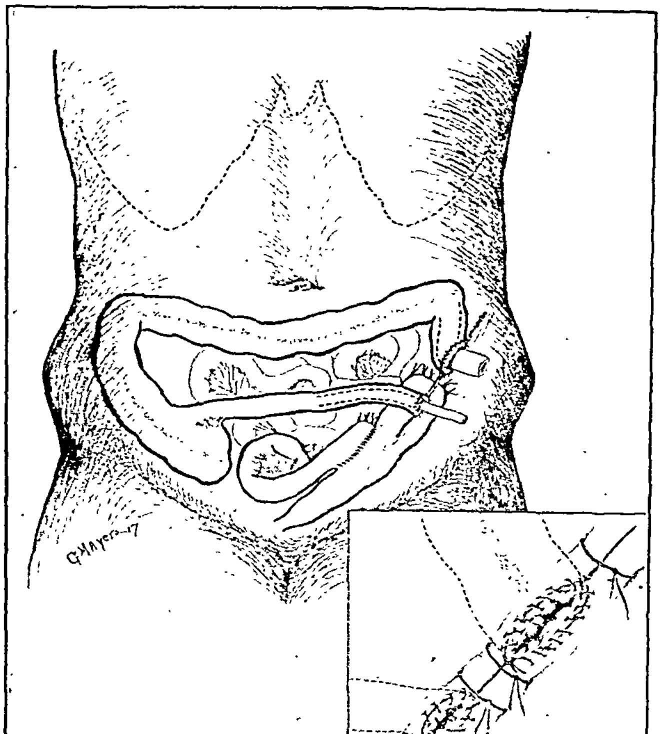

Fig. 8.—Colon exclusion (physiologic colectomy) completed with tube in terminal ileum. A catheter is generally used and carried through the ileocecal valve into the cecum. The effluent tube is seen in the open end of the colon. The method of fixing the open ends to the skin is shown in the lower right hand corner. (First method.)

3. Dissect both of the divided ends of the bowel from the mesosigmoid for a distance of at least an inch.

4. Reunite the divided ends of the sigmoid by means *of a Murphy button smaller than the natural lumen of the intestine.*

5. As soon as the button is clamped, invaginate it into the distal sigmoid to the depth that it will go—probably an inch.

6. Make this intussusception permanent by stitching the margin of the fold to the wall of the invaginated portion, using preferably fine but strong Japanese silk for the purpose.

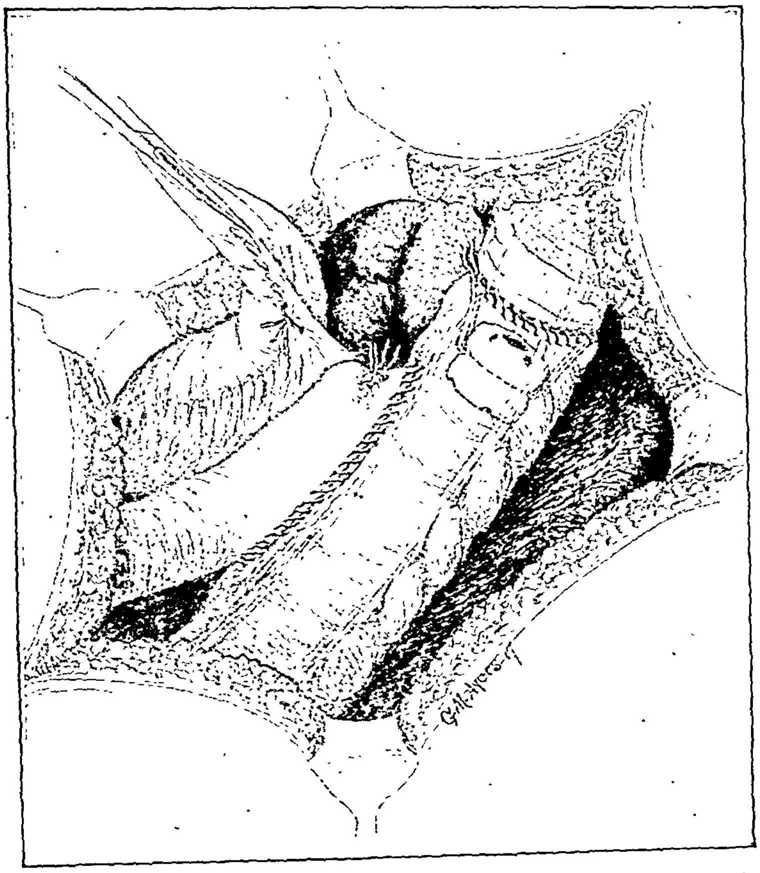

Fig. 9.—Ileosigmoidostomy with side-to-side anastomosis and sigmoidosigmoidostomy with circular intrasigmoidal valve to prevent anastaltic filling of the disused colon. (Second method.)

7. Stitch the open end of the terminal ileum into the lower angle of the wound.

8. Insert a large catheter through the terminal ileum into the cecum.

9. Insert a large rectal tube up to but not through the anastomotic orifice, the perforations in the tube extending down nearly to the level of the levator ani muscle.

10. The wound, after being thoroughly cleaned with chlorazene solution, is closed with laminated chromic gut, fortified with a few silkworm sutures and dressed with gauze saturated with chlorazene.

The patient should be given a liquid diet for a few days, there being no hurry to stimulate the normal peristalsis of the small intestine. Irrigations through the ileocecal catheter should be deferred for from six to eight days, or in the absence of symptoms, until the button comes away. They may then be inaugurated by throwing into the cecum about 4 ounces of some one of the numerous liquid petrolatums. This may be repeated every six hours until the contents of the colon have become at least semiliquid and will drain away through the rectal tube. The rectal tube itself, inserted at the time of operation, should be kept in for at least ten days, and should be removed only for purposes of cleansing. After its first removal following the establishment of fecal drainage, no attempt should be made to reinsert it for a distance of more than 4 inches. The ileocecal tube should be kept in and the irrigations continued for several weeks or months, after which the ileac orifice may be closed or permitted to close spontaneously.

The argument in favor of this procedure is that: 1. It is obviously safe. I have so far done it in only five cases, but in each instance without the slightest difficulty. 2. The valve formation is apparently effective against anastaltic pressure as, following the primary cleansing of the colon, no fecal matter has been detectable through the ileocecal tube. 3. If the drainage of the colon is thus permanently secured without the danger of anastalsis, there is no obvious reason why the large bowel should ever be removed. The argument against the procedure is that it is not available in cases in which the sigmoid is short or buried in fat or bound down, literally buried, by adhesions of an old perisigmoiditis. The chief argument against it as a primary procedure is that in the subsequent prolonged drainage of the colon, the highly toxic mucus must come down through the rectum from which it is absorbed with facility. In this particular, colon exclusion with external drainage is obviously superior.

THIRD METHOD: PHYSIOLOGIC COLECTOMY WITH LATERAL TRAP-VALVE IN THE SIGMOID

In three cases the conditions just described, namely, short sigmoid buried in adhesions, made it impracticable to apply either the first or the second method just described. In these circumstances, I had recourse to a technic which may be carried out as follows:

1. Do an ileosigmoidostomy as described in this paper.

2. Divide the anterior wall of the sigmoid at a point as far as possible above the anastomosis, carrying the incision through all the layers from outside of one tenia to a similar distance outside the other tenia.

3. Closely whip-stitch the margin of the upper lip of the wound.

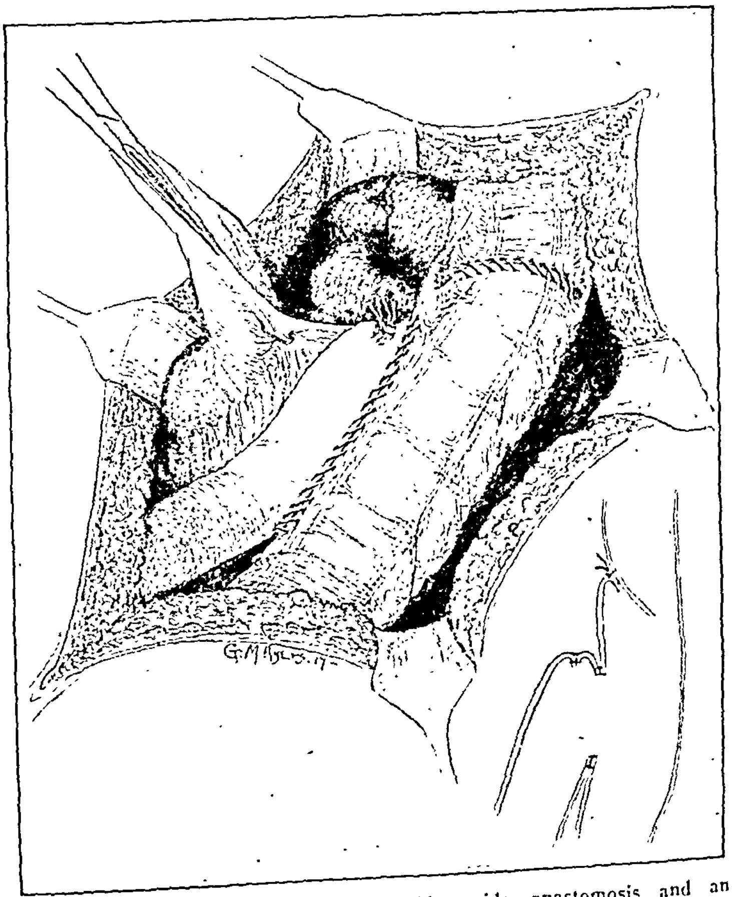

Fig. 10.—Ileosigmoidostomy with side-to-side anastomosis and an infolding flap of sigmoid for formation of trap-valve to prevent anastaltic filling of the unused colon.

4. Bring the lower lip of the wound up to a point about an inch above the margin of the upper lip, and stitch the former to the peritoneal surface by a double row of fine but strong Japanese silk.

5. Conclude the operation in all other particulars as described in the "second method."

The argument in favor of the method first described is that it can be done under anatomic conditions when neither of the other methods is available. It is simple and seems to have been effective in the cases in which I have employed it. The argument against it is that the suturing may give way under violent anastalsis just as in the first method. This accident has not been encountered in my brief experience with this particular technic. The valve formation may not be as effective as the circular valve secured by the second method. In any event, it would seem that the condition established by the operation is sufficient to inhibit the anastaltic wave while not interfering with the peristaltic wave from the cecum to the sigmoid. If further experience shall confirm this conception, the procedure just described may become the one of election in physiologic colectomy.

FOURTH METHOD: PHYSIOLOGIC COLECTOMY BY END-TO-END ILEOSIGMOIDOSTOMY AND SIDE-TO-SIDE SIGMOIDOSIGMOIDOSTOMY.

The very interesting experimental studies in anastalsis and therapy of the colon by Lynch and Draper[3] resulted in the suggestion by them of a procedure to block the anastaltic wave. This procedure, as I understand it chiefly from the illustration accompanying their article, may be described as follows:

1. The ileum is divided near the cecum, and the orifice of the distal segment is closed.
2. The sigmoid is divided about its middle, and both ends are closed.
3. An end-to-side anastomosis is effected between the proximal ileum and the upper end of the distal segment of the sigmoid.
4. A side-to-side anastomosis is then done between the two segments of the sigmoid, the stoma being located well below the ileosigmoidal connection.

The valvelike arrangement effected by the slit connecting the two segments of the sigmoid may serve effectively to prevent reflux into the upper colon while not interfering with efflux from it. *In any event, it* is evident that the continuity of the anastaltic wave is intercepted by the division of the intestine and the lateral anastomosis. There are, however, many sigmoids in which this procedure cannot be carried out. It would seem, too, that the closed end of the distal sigmoid is subjected to dangerous anastaltic pressure. It is evident, too, that the *procedure must involve* tedious details and consume much time. On its experimental basis, however, it stands as an interesting confirmation of the principle for which I contend.

CONCLUSIONS

In summarizing my experience so far I may say that it has led to at least tentative conclusions as follows:

1. Patients with intestinal stasis should be treated first by dietetic and hygienic measures, including massage and support, until and only until the inutility of such procedures has been demonstrated in the individual case.
2. Colon fixation with incidental anchorage of the stomach when properly done is at once striking and permanent in the relief afforded, and being conservative, is to be recognized as the operation of choice in all but extreme cases.
3. Physiologic colectomy with valve formation just above the sigmoid may well be done as a safeguard against anastalsis in cases of ptosis of the colon, causing glandular hypertrophy which has further resulted in a marked catarrhal colitis associated with atrophy of the muscularis of the colon.
4. Physiologic colectomy with external drainage through the distal ostium of the colon should be done *only* in extreme cases, and then only with the understanding that it is to be followed ultimately either by (*a*) reestablishment of the colonic canal with valve formation at the point of anastomosis or by (*b*) the complete removal of the colon.

THE VALUE OF THE WASSERMANN REACTION

A REPLY *

JOHN A. FORDYCE, M.D.
Professor of Dermatology and Syphilology, Columbia University, College of Physicians and Surgeons; Visiting Dermatologist, City Hospital

NEW YORK

In an article on the value of the Wassermann reaction, as indicated by postmortem investigation in 331 cases at Bellevue Hospital, Symmers, Darlington and Bittman[1] have made an attempt to correlate with their necropsy findings the results of the Wassermann reaction taken during the life of a patient. They assert that from 31 to 56 per cent. of patients who, during life, gave a negative Wassermann showed *at necropsy positive evidence of syphilis.* A second assertion is that the Wassermann reaction was positive in 30 per cent. of the cases that showed negative findings at necropsy.

The impression made on the reader of the article is that the Wassermann reaction is not dependable in the diagnosis of syphilitic affections, and of little value as an indication of the cure of the individual affected with syphilis. It is true that physicians who are unacquainted with the technic and the interpretation of the reaction have had reason to criticize the conflicting results obtained in many Wassermann laboratories. These contradictory results, however, are largely due to inexperience, carelessness and the failure to develop a technic based on clinical and serologic correlation. The value of the reaction has been determined by the study of thousands of cases clinically, and by the much slower process of comparing the serologic with the pathologic findings. Before the introduction of the Wassermann reaction, our knowledge of syphilis was chiefly centered on the various types of *skin lesions,* with a very meager knowledge of the visceral manifestations. Since then the rôle of syphilis as a causative agent in producing pathologic changes in various organs has been greatly extended. The incentive to this study was the Wassermann reaction, and today many a syphilitic aortitis would go undiagnosed without the assistance of a serologic test.

[1] Symmers, Douglas; Darlington, C. G., and Bittman, Helen: The Value of the Wassermann Reaction as Indicated by Postmortem Investigation in Three Hundred and Thirty-One Cases at Bellevue Hospital, The Journal A. M. A., Feb. 2, 1918,

Why has the Wassermann reaction fallen into disrepute with clinicians untrained in the laboratory side of syphilis? A short summary of the history of the reaction may answer this question. Following the technic as originally laid down by Wassermann, the results of the test agreed surprisingly with the clinical diagnosis of the skin lesions in the different stages of the disease. The serologic method was thus hailed as the final word in diagnosing syphilis. When to this was added further information regarding visceral lesions, such as the frequent association of an aortic insufficiency with a positive Wassermann reaction, the enthusiasm knew no bounds. Four factors, however, soon developed which proved a serious complication:

1. The discovery that the reaction was a nonspecific one.
2. The attempt to modify the reaction so as to make it available to the practitioner in his office.
3. The use of reinforced antigens and other changes in technic to render the reaction more sensitive.
4. The practice by some physicians of sending their blood specimens to commercial in preference to recognized hospital laboratories.

The first factor, the discovery that the reaction was a nonspecific one, was a great disappointment. Nevertheless, while we could not explain why alcoholic extracts gave positive fixations with specific serums, the fact remained that such was the case, and after the first storm of skepticism gradually subsided, the explanation was left for the serologist to determine at a future date. The application of the test is another matter.

The second factor, the attempt to modify the reaction so as to make it available to the practitioner in his office, was and is a serious matter. No one hesitates to admit that the practice of serology entails special training; nevertheless it is astounding how quickly makeshift methods are accepted by the profession. The result is apparent, and needs no further comment.

The third factor, the use of reinforced antigens and other changes in technic to render the reaction more sensitive, has been of great interest and value to the serologist, who has a working knowledge of clinical and pathologic syphilis, but a great stumbling block to the general practitioner, or even to the pathologist, who has not the technical training of the serologist. Many of the discrepancies in the various laboratories are due to the lack of standardization in technic. While some adhere to the employment of either plain alcoholic extract antigens or to cholesterinized antigens with the original Wassermann technic, others use alcoholic antigens with icebox fixation, or one of the numerous other known modifications. These modifications that have been introduced have made the name "Wassermann reaction" ambiguous. Today there are hardly two men practicing the same technic, with the result that there are many discrepancies in their final diagnoses. To the syphilographer and the pathologist trained in serology, these discrepancies are more apparent than real. They know that differences will result when the various modifications are employed. With proper controls and an accurate routine technic, however, each known modification (plain alcoholic extracts or reinforced cholesterin antigens, or both, or the icebox fixation method) give results, which, though not always similar, are, at least, of immense value when properly interpreted and correlated in the light of the clinical evidence. A certain percentage of cases give a positive reaction with a cholesterinized antigen and a negative with the icebox fixation method. Another percentage of cases will react positively with plain alcoholic extract antigens, and negatively with cholesterinized antigens. It is the old and treated cases, especially, that give varying results with the different methods employed. In recent cases of florid syphilis the Wassermann reaction is, as a rule, strongly positive with all antigens. It is imperative, therefore, in order to detect old cases of syphilitic infection, that two or more methods be employed synchronously. The use of cholesterin antigens along with plain alcoholic extracts is an advantage, though a positive result with cholesterin antigens with some serologists is much less conclusive. On the other hand, a negative result with cholesterin antigens is much more desirable from the point of view of the patient. Cholesterin antigens and other sensitive methods often give a positive result much earlier with chancres, and in treated cases the positive reaction persists longer in the majority of them. Numerous other facts could be stated to show the necessity of the proper interpretation of the various serologic methods.

We would suggest, therefore, that when an investigator reports the value of a certain serologic procedure he should not be misleading and report it as the "Wassermann reaction," but state definitely the particular method of the complement fixation employed.

The fourth factor, the practice of physicians of sending their blood specimens to commercial in preference to recognized hospital laboratories, pertains to all laboratory work. In our experience there are few such laboratories that deserve serious recognition.

To meet both the favorable and the unfavorable criticisms of the Wassermann reaction, some plan of study must be formulated, in order to give an idea of the absolute value of any serologic procedure in diagnosing syphilis. Each modification of the reaction has its adherents, and unjustifiable claims are made for each method. The proof that any method approaches technical perfection is no evidence in itself that its application is any improvement over another method. The point in question is merely to prove that one particular technic when applied to the diagnosis of syphilis has unquestionable advantages over any other. To what rigid application, then, must this procedure be submitted?

We name the two following requisites:

Requisites for any serologic procedure
- 1. Its value in diagnosing any known syphilitic lesion
    - (*a*) Chancre
    - (*b*) Skin manifestations
    - (*c*) Visceral syphilis
    - (*d*) Neurosyphilis
- 2. Its value in establishing the presence or absence of a syphilitic infection

We have three direct methods at our command to demonstrate syphilitic manifestations in the body: (1) clinical observation; (2) spirochetal demonstration and (3) pathologic study. With a reasonable degree of accuracy we can diagnose clinical syphilitic manifestations, such as chancre, skin lesions, pronounced aortitis, general paresis and tabes. Many other visceral conditions, such as a latent aortitis, and deep gummas of the liver, too often escape the notice of the most accurate clinical observer. The clinician, therefore, can only partially assist, and then only with those manifestations of syphilis that lend themselves to a definite and accurate diagnosis of syphilis. He is more to be relied on, however, for the value of the Wassermann reaction in diagnosing chancre, than is the pathologist.

VALUE OF WASSERMANN REACTION (Cholestrin Antigens with Warm Fixation, and Plain Alcoholic Antigen Icebox Fixation) IN DIAGNOSING CLINICAL CASES OF UNDOUBTED SYPHILIS

In studying the present records of one of us (Fordyce), the value of the Wassermann reaction (cholesterin antigens and alcoholic extracts with icebox fixation) in diagnosing undoubted clinical manifestations of syphilis becomes quite apparent. In primary syphilis the reaction does not become positive until there is a generalization of spirochetes. This occurs before the appearance of the rash, and the reaction may be positive as early as from ten days to two weeks, or as late as from six to eight weeks after the development of the chancre, depending on the antigens and the technic employed in the reaction.

In secondary syphilis the laboratory that employs correct technic will obtain a positive reaction in 100 per cent. of untreated cases. Our records fail to show a single instance of a negative reaction in such individuals.

In 309 cases of tertiary syphilis with manifest lesions of the skin and mucous membranes, the Wassermann reaction was strongly positive in 283, weakly positive in eight, and negative in eighteen. Of the latter, four became strongly positive under treatment. The percentage, therefore, of negative Wassermann reactions in tertiary syphilis with active lesions is about 6.

The results in 112 cases of tabes were as follows: Fifty-two had positive reactions in the blood and in the spinal fluid; thirty-seven were negative in the blood; of these thirty-two had positive fluids; three with positive bloods gave a negative fluid; four were negative in the blood and fluid. In sixteen with a positive blood, the fluid was not examined. The percentage, therefore, of cases of tabes with a negative blood and fluid is less than 4, and as we recognize an abortive form of tabes, it is fair to assume that the negative ones were either cured spontaneously or by treatment.

In paresis, eighty-one cases were examined with positive blood in eighty and positive fluid in all. It is exceptional to find an untreated case with the objective stigmata of paresis that shows either a negative blood or a negative fluid. In taboparesis, twenty-six cases showed a positive blood and positive fluid.

Of cerebral syphilis, other than the types mentioned, twenty-three cases were examined, eighteen of which were positive in the blood, and five were negative in the blood. Seventeen were punctured, of which fifteen were positive and three negative in the fluid. In cerebrospinal syphilis, fifty-seven cases showed a positive blood and fluid; five a positive blood and negative fluid; nineteen a negative blood and positive fluid, and twelve both negative blood and negative fluid. The percentage of cases of cerebrospinal syphilis, especially of the *vascular type*, in which negative Wassermann reactions were obtained in the blood and spinal fluid is larger, therefore, than in any other variety of syphilis. In these cases the administration of mercury and iodids, together with arsphenamin, activates a certain number of apparently negative cases.

SPIROCHETAL DEMONSTRATION

Spirochetal demonstration, however, as a direct method of demonstrating syphilitic infection is the ideal one. With the exception of open skin lesions this method, unfortunately, is hardly available, though Dr. Warthin[2] reports finding them with remarkable constancy in syphilitic organs. No one else, apparently, has been so uniformly successful, excepting with congenital organs, though the literature throughout the scientific world abounds with numerous attempts.

PATHOLOGIC STUDY

Pathologic study, therefore, is the one method at our command for an accurate estimation of the value of any complement fixation test for visceral syphilis. The importance of such a study is not to be denied, and any scientific report must meet all the necessary and critical requirements to make any conclusions drawn beyond a question of doubt. It is for this reason, therefore, that we feel called on to criticize the remarkable deductions of Dr. Symmers and his colleagues. The conclusions drawn are unwarranted and misleading to the practicing profession. To make our claim good it will only be necessary to analyze their report in detail.

We have already stated that the name "Wassermann reaction" is an ambiguous term. It is necessary, therefore, to study separately the value of each complement fixation method. The two distinct points mentioned in regard to the serum reaction are the use of cholesterinized and alcoholic extract antigens. Nothing is said in the article as to the technic employed. This is an unfortunate and serious omission. Ottenberg[3] has shown in an elaborate comparative study of fifteen distinct modifications of the Wassermann reaction in active use in different laboratories that apparently minor variations in technic, such as different methods of determining the dose of complement, different ingredients, variations in time and temperature of incubation, and even the variation of the order in which the reagents are added, as well as the difference in the kind of antigens used, make an enormous difference in the results obtained. For this reason, he pointed out that no discussion of the reaction could be of any value, unless accompanied by an accurate protocol of the method used. Since the various modifications give different results, it is obviously essential in comparing serologic results with pathologic data, that the problem should be a study of the value of all the recognized and type methods of serologic procedure. Only in this way can one arrive at any definite conclusions.

We first review the figures on the alcoholic extract antigens, which we have compiled from the protocol in the article under discussion.

VALUE OF THE WASSERMANN REACTION (Plain Alcoholic Extract Antigens, Warm Fixation) IN DIAGNOSING AN UNDOUBTED SYPHILITIC VISCERAL LESION (Pathologic Study)

A review of the recent literature reveals that the results obtained show a remarkable discrepancy with those reported by Dr. Symmers and his co-workers. Gruber,[4] studying 106 cases of syphilitic aortitis pathologically, obtained 94.3 per cent. positive fixations on postmortem serums when employing alcoholic extract of syphilitic livers as antigen. Curiously enough, in a study of syphilitic aortitis we (Larkin and Levy[5]) obtained identical results (94 per cent.) on antemortem serums, using as antigen the alcoholic extract of guinea-pig heart. From the table submitted by Dr. Symmers and his co-workers, in thirty-two cases of syphilitic aortitis, in which the serum reaction was reported with alcoholic antigens, only 56 per cent. of the serums gave positive reactions. In all cases, with so-called positive lesions of syphilis they obtained the strikingly low figure of 53.8 per cent. positive reactions with the alcoholic extracts. The reasons for this we can only suggest. To criticize a serum test that is not described is, of course, difficult. Nevertheless, if others can obtain much better results with identical antigens, one must assume that some error in the technic is responsible, and that better serologic results should have been obtained. On the other hand, can we question the pathologic diagnoses? Though the gross picture of syphilitic aortitis is characteristic, and can often be diagnosed by the naked eye, nevertheless arteriosclerotic changes may so obscure the picture that the diagnosis may be extremely difficult, and could be made only by histologic examination. No mention that this was done is made. Further, the possibility of error in the diagnosis is quite apparent from the fact that the organs were not all personally studied by the authors, but the data as given on the records accepted, in some cases, as final. The fallacy of such a procedure for detailed study of any subject is not to be denied.

VALUE OF A POSITIVE WASSERMANN REACTION (Plain Alcoholic Antigen, Warm Fixation) IN ESTABLISHING THE PRESENCE OF A SYPHILITIC INFECTION

In considering cases with positive serum reaction, which showed on postmortem examination the presence or absence of specific changes, again one finds results that do not agree with the experience of others. Using alcoholic extract antigens, Dr. Symmers and his co-workers found that in fifteen cases with positive serum reactions, only 75 per cent. revealed postmortem evidence of syphilis; we (Larkin and Levy[5]) in seventeen cases were able to find evidence of syphilis "in the aorta alone" in 90 per cent. of the cases. It is stated that "we shall hope not to leave it to be read between the lines that our technic has precipitated certain exceedingly regrettable mistakes." It is self evident, however, that there have been, at least, omissions of acute observation and study of the pathologic material and the recent literature on the subject. In the article space is devoted to a discussion of the failure of spirochetal demonstration, and not a word is mentioned as to the histologic examination of organs in search of the presence of syphilis. The fallacy of diagnosing the absence of syphilitic infection merely by gross examination of organs has been pointed out by several workers. It is now a matter of general knowledge that syphilis incites a productive inflammatory reaction, which, only in certain organs, is characteristic and diagnostic, and that these changes may be present in an organ without producing any gross manifestations discernible by the naked eye. We (Larkin and Levy[5]) have reported evidence of this both in the aorta and the nervous system. Dr. Larkin has in his collection type cases, such as the following:

> A woman, aged 26, died of a cardiac condition, with positive serum reaction before death. At necropsy the heart showed evidence of an infectious endocarditis. The aorta appeared normal. But on histologic examination the diagnosis of syphilis was unquestioned.
>
> In a patient dying of a ruptured aneurysm, the spinal fluid had given positive findings antemortem. Gross examination of the cord and brain revealed nothing abnormal. After a painstaking and exhaustive histologic examination an early sclerosis of the posterior nerve root ganglion cells was found.

In view of these facts, it is easy to understand the surprisingly low percentage which Dr. Symmers and his co-workers found when checking up the positive serum reactions with evidence of syphilis at necropsy. Those cases in the protocol which have been designated as having "no signs of syphilis" might very well reveal histologic changes in the aorta that are pathognomonic of syphilis, though to the naked eye the aorta may appear normal.

No mention is made of the possibility of dealing with latent syphilis in reporting such a high percentage of positive serums in apparently normal individuals. Neither is there any report given of spinal fluid examination, or findings in the brain and cord. One might, therefore, suspect a latent infection, or draw the conclusion that normal serums were examined with a highly sensitive cholesterin antigen, since the majority examined with an alcoholic extract antigen gave a negative result, and that false positives were obtained. To exclude syphilis at necropsy beyond a question of doubt would mean an amount of work that is physically impossible in the laboratories connected with the pathologic departments of the various hospitals. It would be necessary, in the first place, to exclude involvement of the nervous system, which, in a certain percentage of cases, shows involvement, even in the absence of visceral syphilis. It is well known that shortly after the appearance of the initial lesion in experimental and acquired syphilis, the lymph nodes, bone marrow and spleen may harbor spirochetes, and from our knowledge of the syphilitic process it is fair to assume that in certain cases these organisms may persist in these regions for an indefinite length of time. Have the authors of "The Value of the Wassermann Reaction" examined the lymph nodes, the bone marrow and the various other possible sites of spirochetal selection in their necropsy work?

If, in the four cases in which Dr. Symmers and his colleagues found no evidence of syphilis, an examination, microscopically, of the aortas alone had been made, the conclusions arrived at might have been different. A positive diagnosis in two of these four cases may have given a percentage approximating the 90 per cent. found by us.

CHOLESTERIN ANTIGENS

In studying the results of the cholesterin antigens, as tabulated in the protocol, one cannot but help seriously questioning the accuracy of the serum reactions. In a series of fifty-one cases, in which both antigens were employed, identical reactions were obtained in only fifteen cases. In other words, there was a discrepancy in 70 per cent. of the cases. It is obvious that the technic employed with one or the other of the antigens (if not with both) was faulty. Practically no other worker who has compared the two antigens has obtained anywhere nearly so large a discrepancy. Ottenberg[6] has found not more than 15 per cent. difference.

[4] Gruber: Ueber die Doehle-Heller'sche Aortitis, Jena, 1914.

[5] Larkin, J. H., and Levy, I. J.: A Pathological Study of Syphilitic Aortitis and Its Serology, Jour. Exper. Med., 1916, 23, 25.

On analyzing the results of the cholesterin antigens with the necropsy findings, we note, when summing up all the positive cholesterin reactions (that is, positive, strongly positive and very strongly positive) that only 47 per cent of the reactions had postmortem evidence of syphilis. We[5] accounted for 77 per cent. of our positive reactions by histologic examination of the aorta alone. Again we must assume faulty technic in performing the serum tests, or careless and inaccurate pathologic observation.

In regard to the statement that "the Wassermann reaction in the living patient is positive in at least 30 per cent. of the cases in which it is not possible to demonstrate any of the anatomic lesions of syphilis," the lack of appreciation of the existence of the several methods of performing the Wassermann reaction is evident. We have here an average of the results obtained by using two widely different serologic methods, instead of noting definitely the results obtained by each method. If we should employ this fallacy we would have 17 per cent. of our positive reactions unaccounted for by syphilitic changes in the aorta (the average of 10 per cent. alcoholic extract antigens and 23 per cent. cholesterin antigens).

VALUE OF A NEGATIVE WASSERMANN REACTION (PLAIN ALCOHOLIC EXTRACT ANTIGEN) IN ESTABLISHING THE ABSENCE OF A SYPHILITIC INFECTION

(FROM PRESENT DATA)

One could have accepted the study of Dr. Symmers and his co-workers as a fair attempt to correlate positive serum reactions with postmortem findings, if they had not drawn such definite conclusions, and at the same time felt called on to give the practitioner such revolutionary advice about the Wassermann reaction. Surely when they discovered the positive phase of the reaction was so misleading and confusing, a negative result, on the other hand, may at least be of some value. This they apparently omitted to consider. To condemn a laboratory procedure on data not complete and comprehensive is a fallacy that is not altogether pardonable. By other men, however, the negative phase of the reaction has been touched on; and, surprising as it may seem, suggests that a negative Wassermann reaction is of certain value in eliminating the presence of syphilis.

In a study of twenty-four aortas, in which there was no perivascular infiltration, the serums, antemortem, of these patients gave a negative reaction in twenty-two (Larkin and Levy[5]). In a comprehensive study of all the organs of the two positive serologically we might have been successful in finding pathognomonic evidence of syphilis. This, however, was not done. Nevertheless, in the study of the aorta alone the absence of syphilitic infection gives a negative reaction in probably about 91 per cent. of the cases (Larkin and Levy[5]).

QUESTIONABLE SYPHILITIC PATHOLOGIC DIAGNOSES

Further, in studying the protocol of Dr. Symmers and his colleagues, we find under "Necropsy Findings" the following: "No signs of syphilis, smooth indurative atrophy of the tongue, syphilitic orchitis, syphilitic osteitis, scars on shin," etc. The authors admit the difficulty of interpreting syphilitic changes in organs of syphilitic individuals. They fail to recognize the fact, however, that in estimating the value of any laboratory procedure in diagnosing the etiology of pathologic changes in organs that this etiologic factor must produce physical changes in organs that are characteristic and pathognomonic, and these changes must be present with a fair degree of constancy. The reverse is true in the absence of the infectious agent. It is a great fallacy to diagnose the presence of syphilitic infection by physical changes in organs that are not of undoubted syphilitic origin. It is just as great a mistake to negate syphilitic infection, unless there is a thorough search, microscopically, for the characteristic physical changes produced by syphilis. The conclusion "no signs of syphilis" has no meaning, unless we are assured of such an inspection.

Dr. Symmers,[7] individually, on two or three previous occasions, and now with his collaborators,[1] warns the clinician, and advises distrust in the use of the Wassermann reaction. He forgets that the most constant symptom of syphilis is a positive Wassermann reaction. The folly of insisting on the importance of a healed scar on the penis, atrophic pigmented scars in the pretibial region, or a roughening of the anterior border of the tibia as diagnostic phases of syphilis is too evident to all syphilographers. That syphilis may produce these lesions has been known for years; but other infections often are causative factors. Tuberculosis, chancroidal ulcers and pyodermias may lead to scarring of the genital organs. We frequently see pigmented scars in the pretibial skin due to ecthyma, tuberculous ulceration and to infected injuries, which present all of the characteristics of syphilitic scars. And when one recalls the invariable absence of these signs in practically every known phase of syphilis, one wonders if Dr. Symmers is asking us to take a step backward to the dark ages for our method of the diagnosis of syphilis. The same applies to superficial lymphadenopathy. Increased consistency and diminished sensitiveness of one or both testes would scarcely appeal to the clinician as an evidence of syphilis of these organs. Leukoplakia of the mouth and tongue is by no means the invariable consequence of syphilis. It is frequently seen in individuals who have never been infected. Syphilitic orchitis and syphilitic osteitis suggest physical changes in these organs, the etiologic factor of which could easily be questioned. Scars on the skin present nothing characteristic to prove that they are of syphilitic origin, though they very well could be considered as evidence. Scars of old syphilis may exist at necropsy in persons in whom the spirochetes and infection had disappeared. These persons may have suffered from syphilis, but the scar is the end-result of a syphilitic process. We not infrequently see patients with multiple scarring of the skin, pigmentation or characteristic changes in the mucosa, who are cured of their infection.

Before classifying necropsy cases as showing positive evidence of syphilis, it is exceedingly important to distinguish between active progressive lesions or healed and nonprogressive ones. We should also have the data as to the influence of treatment before the

---

[6] Verbal communication.

[7] Symmers, Douglas: Anatomic Lesions in Late Acquired Syphilis, The Journal A. M. A., May 6, 1916, p. 1457; Syphilis as an Etiological Factor in Laennec's Atrophic Cirrhosis of the Liver, Internat. Clin., 1917, 1, 58.

Wassermann reaction was taken. Dr. Symmers and his colleagues apparently ignored entirely the amount of treatment that any of the cases reported with positive clinical evidence may have received. Surely they must be familiar with the fact that reversal of the reaction may occur *after therapeutic* administration, though anatomic residua may persist.

Lichen planus, tuberculosis, *lupus erythematosus*, and pemphigus of the mouth and tongue may at times *closely simulate* the syphilitic process, and can be differentiated only by a careful correlation of the clinical manifestations aided by the Wassermann reaction. We (Fordyce) have seen in our clinical and pathologic work fully as many errors made by relying on the clinical signs as we have seen made by a wrong interpretation of the Wassermann reaction, if not more.

As an evidence of the persistence of spirochetes in the body, and as a guide to cure, the Wassermann reaction is of vastly more importance than the clinical observation alone. We have seen in the past years many patients treated by the old clinicians and discharged as cured of their syphilitic infection, who have returned with involvement of the central nervous system, cardiovascular system and other syphilitic affections revealed by a positive Wassermann reaction and objective evidences of the disease. If these patients at that time had been properly controlled by the serologic tests, it is fair to assume that a large percentage of them would have been cured of their infection.

After the earnest endeavors made to teach the proper evaluation of the Wassermann reaction, it would be a great pity if the article by Dr. Symmers and his colleagues were taken too seriously by that part of the profession which has not had the proper training in both laboratory and clinical interpretation. The impetus given to the study of neurosyphilis has been based largely on the findings in the spinal fluid, especially in the secondary stage of syphilis. Without the Wassermann reaction and the training necessary to interpret its significance, many patients who are positive serologically only in the spinal fluid would be denied the treatment that will cure their condition, and will be permitted to develop the various chronic nervous diseases, such as tabes and paresis, as in the past.

The old rule, too, which related to the marriage of syphilitics often led to the most disastrous consequences. A patient under the old clinicians was given permission to marry from thee to five years after his syphilitic infection, if he had been free from symptoms during one year before marriage. We have seen a number of men acting on such advice, who married from five to eight years after their syphilitic infection, transmit syphilis to their offspring. On the contrary, we have known a number of instances in which persons, cured by modern methods, married two years after their infection and procreated healthy children. In the latter group of cases a cure was obtained serologically; in the former group, only a so-called clinical cure had been brought about. The Wassermann reaction, therefore, as a guide to marriage is of vastly more importance than the element of time.

The article by Dr. Symmers and his colleagues is, in our opinion, filled with erroneous deductions; and so far as it tends to discredit the value of the Wassermann reaction as a guide to the existence of syphilis and as a criterion of cure, it will mislead that part of the profession which is not trained to interpret and correlate laboratory and clinical findings, and is easily influenced by work carried out in institutions of the dignity and age of Bellevue Hospital.

REQUISITES FOR SEROLOGIC PROCEDURE

- Requisites for *any* serologic procedure
  - Its value in diagnosing any known syphilitic lesion
    - Clinical cases of undoubted syphilis (Cholesterin antigen; warm fixation) and (Plain alcoholic extract, icebox fixation)
      - Chancre: 95 - 100% positive reactions, depending on age of lesion
      - Secondary syphilis: *100% positive* reactions
      - Tertiary syphilis: 94% positive reactions (late skin and mucous membrane manifestations)
      - Neurosyphilis:
        - Paresis: 99% *positive* reactions *(blood* and spinal fluid) 81 cases
        - Tabes: 50% positive reactions (blood and spinal fluid), 96% *positive reactions* (blood or *spinal* fluid), 60% positive reactions *(blood)*
      - (Cerebral syphilis)
    - Visceral lesions Pathological study (Plain alcoholic extract antigen; warm fixation)
      - Aortitis: 94% positive reactions
  - *Its value in establishing* the presence or absence of a syphilitic *affection*
    - *Value of a positive* Wassermann reaction in establishing the *presence* of a syphilitic affection (pathologic study)
      - Alcoholic extract antigen: Percentage of reactions showing evidence of *syphilis: in* the aorta, 90%
      - Cholesterin antigen: In the aorta, *77%*
    - Value of a negative Wassermann reaction in establishing the absence of a syphilitic affection
      - No definite figures are obtainable:
        - (a) Reliability confirmed by the negative reaction obtained in nonspecific skin lesions
        - (b) In a series of aortas free from syphilitic disease the serum, antemortem, was negative in *91.5%* of cases

SUMMARY

The term "Wassermann reaction" includes several methods of serologic procedure. An accurate interpretation of each method is essential in arriving at a proper diagnosis.

A positive reaction is the most constant symptom of syphilis.

The value of the reaction in diagnosing undoubted syphilis is shown by the fact that:

1. The reaction is positive in practically 100 per cent. of the cases of florid syphilis.
2. In active tertiary syphilis of the skin and bones the reaction is positive in about 94 per cent. of the cases.
3. In syphilis of the central nervous system, cognizance must be taken of the reaction in both blood and spinal fluid. The blood is positive in about 80 per cent. of the cases.
4. In a pathologic study, the Wassermann reaction (alcoholic antigen, warm fixation) was positive in 94 per cent. of cases of syphilitic aortitis.

As a means of corroborating syphilitic infection, the Wassermann test is at least 90 per cent. dependable, as shown in a series of positive reactions in which 90 per cent. could be accounted for by syphilitic changes in the aorta alone.

The value of a negative reaction has been studied and its reliability confirmed by the negative reactions obtained in nonsyphilitic affections of the skin. In a series of necropsies in which it was demonstrated pathologically that the aorta was free from syphilitic disease, negative reactions were obtained in 91 per cent.

The conclusions of Dr. Symmers and his co-workers are shown to be fallacious and a misrepresentation of facts owing to:

1. The apparent disregard of the different results obtained by various serologic methods and the employment of a questionable technic.
2. The careless survey of pathologic material.

PRIMARY UNILATERAL OPTIC ATROPHY IN A CHILD, FOLLOWING FRACTURE OF THE SKULL

AARON BRAV, M.D.
Ophthalmologist, Jewish Hospital
PHILADELPHIA

REPORT OF CASE

M. S., girl, aged 4 years, was sent to me for examination by Dr. Nichols, April 14, 1918. The child had been run down by a motor truck and knocked unconscious, November 10. She was taken to the Polyclinic Hospital. The hospital record shows that she was still unconscious when she got there. There was bleeding from the nose and ears. The right eye was swollen and chemosed so that the pupillary reaction could not be noticed, but the left pupil reacted well. Roentgenoscopy revealed a fracture of the base of the skull as well as the frontal bone into the frontal sinus. The child was in the hospital four weeks and discharged. There was no ophthalmoscopic examination made. When I saw the child about five months later, I found the following ocular condition: right pupil 3 mm., left pupil 2 mm., reaction in right eye sluggish. There was slight muscular deviation showing an insufficiency of the right internal rectus muscle. Ophthalmoscopic examination (under a mydriatic) revealed the media clear, the disk well defined, somewhat excavated and bluish pale, and the retina normal. Though the child was too young for visual examination, I made the following successful tests: When I held a pencil to the left beyond the median line, the child could see it without turning its head. But when I held the pencil to the right beyond the median line, the child had to make a compensatory head movement to see the pencil, indicating that the right eye was probably highly reduced in visual acuity. I then tied the left eye and asked the child to find the father, who was present at the examination. The child attempted to comply and walked into the chair and into the table standing near by. A diagnosis was made of primary optic atrophy caused by the fracture of the skull.

COMMENT

Primary optic atrophy in children is very rare. In adults it is seen not infrequently in tabes, multiple sclerosis and cerebrospinal syphilis. It may even be the first sign that leads one to suspect tabes or cerebrospinal syphilis. Of course, this form of atrophy, when of constitutional origin, is usually bilateral, affecting both eyes simultaneously or at an interval of a short period. Whenever we find a unilateral primary optic atrophy, we must always think of a possible injury to the skull. Primary atrophy in children probably never occurs as a constitutional condition, but may be caused by trauma. This trauma may affect the optic nerve directly, causing disorders such as laceration of the optic nerve, or indirectly, as a result of some pressure resulting from the injury. The pressure exerted on the nerve in unilateral atrophy is usually anterior to the chiasm and is due to hemorrhage. The hemorrhage may be in the orbital cavity, flowing into the sheath of the optic nerve. The fracture may, of course, also involve the orbital bones. The prognosis in these cases is very grave, as they usually lead to blindness. I saw this patient five months after the injury, so I do not know when the atrophy began. As I have nowhere seen any record of primary atrophy of the optic nerve in a child so young, the case deserves to be recorded.

917 Spruce Street.

Military Medicine and Surgery

ALL YEAR MEDICAL STUDY AND THE EDUCATION OF MEDICAL OFFICERS

GEORGE DOCK, M.D.
ST. LOUIS

We in America should be used to making changes in the medical course. We have seen the benefits from rearranging; we are hospitable to new proposals. Do we discuss such proposals as freely as they deserve?

This thought is raised by the paper read by Major H. D. Arnold[1] at the Conference on Medical Education, held in Chicago in February.

Major Arnold's plan, in brief, is to compress medical education into three years, in such a way that next year classes will be graduated four months ahead of the schedule, and each succeeding year another four months earlier, up to the end of three years.

There was very little discussion over this novel plan. Many of those who spoke left the main subject and dilated on the waste of time in vacations by teachers and students, the extravagance of empty class rooms, etc.

As it offers so many different advantages, it will not be surprising if Major Arnold's plan, with or without modifications, is put into effect. If so, I am sure all medical educators will do their best to make it a success. Nevertheless, I believe it may be useful to discuss some of the details, whether it is adopted or not, for they illustrate some important phases of education.

All will agree with Major Arnold that the present standard in medical education must be kept up, and that no concession should be made to those who raise the specious plea of war need, to lower the standards of entrance and of graduation.

No doubt many medical teachers will approve the control over medical schools exercised by the Surgeon-General of the Army (though there seems no reason why the Navy and the Public Health Services should not be concerned), and hope that in time some equally powerful authority will deal with secondary education. Seeing, too, that the federal government will have to supervise medical studies from the beginning, one must hope that it will soon be brought to see the necessity for universal service.

Here a comment may be made on one item of Major Arnold's address — that in which he contrasted the medical student and his long vacation with the soldier and his constant service. The comparison seems unfair. The medical student's work is always fairly strenuous; soldiers do have periods of idleness. Soldiers occasionally have furloughs; Major Arnold's plan would not permit anything like furloughs to medical students. In another point the treatment of the medical student seems unfair — if he cannot keep up with his class he is sent to the ranks. He could not complain if all were treated alike; but why not apply the same rule to professional loafers, the large class of low parasites, the "workmen" whose "helpers" do all their short stint, and those who strike for frivolous reasons?

---

[1] Arnold, H. D.: Medical Education, Medical Interns and the War, The Journal A. M. A., Feb. 16, 1918, p. 451.

In the discussion of Major Arnold's plan one can touch two distinct topics — compression of the course from four to three years, purely as a war measure, and teaching all the year round, without any connection with war, but as a means of using buildings and apparatus more economically. The latter may be considered first, as a sort of amendment to an original motion. Much that has been said about continuous teaching is the by-product of the irrational plan we have worked into in the last third of a century. The "nine months course" — really about eight in most schools — has been made the ideal. No doubt the college term had most to do with the plan, and this left the hot summer months vacant. It gave a longer study time than that adopted in some other countries, and if a long term is the best way to cover much work, one could forgive a plan that made the term otherwise rigid and unpractical. A little consideration of the facts will show that a longer term does not necessarily mean more work.

In the Central Empires the total official course is about seven months, but much of the best work is done in the vacations of two or two and a half to three months. Many laboratory and other practical courses are then given. No one thinks of closing up laboratories. Those who wish to work for a month or even a whole vacation can arrange to do so, and many men, of all ranks, go away to work in other laboratories with different men. This is one incentive to the migration that so widens the intellectual horizon of the undergraduate. An excellent opportunity also is given to teachers for seeing the work of one's colleagues in their own or in allied fields. The official work in the summer semester ends there in the middle of July. Our summer vacation is so timed that not enough cool weather is available at either end, in many places, for serious work. In some places the time from the middle of June to the end of July could easily be used for practical or intensive didactic courses; in others, all of September; in still others, both periods. But almost anywhere in the United States the continental division of time could be followed.

Those who took their undergraduate work in this country before the nine months' plan was adopted must wonder at the idea consciously or unconsciously suggested by those who now speak for long terms. In those early days there was plenty of work, and all who hoped to make themselves useful took special courses that quite made up a nine months' course.

Absence of necessary relations between length of term and amount of work done per year was recognized outside of medical schools. I have recently heard that the University of Toronto had a seven months' course, but all students who tried for honors worked most of the remaining five months, and my informant, a prominent humanist, tells me that his best work was done when he read at night and thought over his reading next day behind the plow.

The idea that study or other work is done only in school time has, I think, a close relation with another idea too widely held — that study ends at commencement time. Overcoming this belief will open a new intellectual world.

To recapitulate the foregoing, it is better to have two (at least) terms than one; better to have two vacations a year than one, provided the shortest is not less than six weeks. Such terms would facilitate migration by undergraduates, and visiting or exchange among investigators as well as teachers of all grades.

I am quite prepared to hear objections raised to these proposals, but these objections will merely indicate the Chinafication that has impressed itself on us as a nation in other lines besides medical education.

A different method from that mentioned has been in existence more than a quarter of a century in the University of Chicago, as was stated by several speakers at the conference. In the quarterly system the continued use of the plant is secured, and although the scheme is not so elastic as the continental plan, it gives the teacher, within certain limits, an opportunity of taking time off when he can do something more than what is offered by summer vacation, and gives the undergraduate a chance for migration, though with little hope of getting what he wants without loss of time, as long as there are no other schools with identical terms.

As to the matter of compressing work into three years as a war measure, the question whether state laws would permit such a change seems hardly worth discussing in war time.

The lack of vacations for the teachers is not to be looked on as serious. The teachers who remain at home are for the most part hardened; they do not all get vacations now; they can forego extensive time for private research even during a long war. The younger graduates, who should be doing the most active research work, are all away working at special subjects. The undergraduates can stand the continuous work. Many of them work all summer as it is, and did so in peace time. That they can do as well under the proposed plan I do not believe, but the experiment would be useful. Even those who before the war worked in summer had a change, had the stimulus of new surroundings in hospitals or elsewhere, and had time to digest what had been taken in large and often indigestible quantities in the preceding term. Under the new plan there will be less chance to make up for inevitable deficiencies in class work, and the suggestion by Major Arnold of a period for making up cannot easily be fitted in with the swift tempo of all year round work.

The division of the year into three terms of four months each will not lend itself to the schemes now successfully followed in some medical schools in which intensive clinical work is taken for periods of three months. The quarterly system would be much better in that respect, and would of course bring about an equally rapid production of graduates.

To my mind the most serious fault in the scheme is what it overlooks in physical training and military training. Medical students even now are not able to take as much exercise or athletic work as men in other departments. With a continuous term I think the outlook would be even worse. Men would therefore leave the medical school, go at once into a hospital or laboratory for a year, and then, without a pause, at the age of 25 or 26, begin the severe physical and mental work of Army surgeons.

In the past year it has been shown that medical officers require from three to eight months to get broken into their duties. It would seem much more rational, on physical and technical grounds, to prepare for military life gradually, following a plan that was suggested at the conference but was not discussed.

Let the colleges retain their present terms until a better plan can be adopted. Send all medical students, about the middle of June, to camps of instruction and keep them there until a week or two before the fall term. In the first summer let the training be physical and military. The latter not to make soldiers, but to give knowledge of the soldier's activities and the soldier's "smartness" to the future medical officer. Setting-up drill, sports, swimming, riding, fencing and rifle and revolver practice could be learned, with the school of the soldier. The training then begun would never be forgotten.

In the second summer put the men in hospitals at training camps. Continue exercise, and train in the work of hospital orderlies, so as better to teach others. Many medical officers do not know how a stretcher should be carried or how a patient is put from a stretcher on a bed. Part of the "paper work" could also be learned at this time. Tedious as this work is, it is necessary, and much less tedious if really known.

In the third year, also in hospitals, as assistants, the more medical duties as well as "paper work" could be finished, with exercises and sports as before.

At the end of the intern year the young medical officer could at once take up his work, and be physically, militarily and medically much more useful than he is now.

The training could be much less costly than at present. Undergraduates would have the status and pay of enlisted men. Healing of accidents, such as broken bones and loss of time from appendicitis or hernia operations would not be so costly as at present.

It has been objected that it would be expensive to send medical students off to camps. It should not be. Most medical schools are near war camps. Inaccessible desert camps need not be used, and even if some expense is entailed by traveling, the amount would be trifling in the total cost of military training.

Medical Journalism in Mexico.—The medical journals have had a hard time of it in Mexico during the unrest of the last few years, and few numbers have been issued. Among them have been the *Escuela Medico-Militar* and the *Gaceta Medica de Mexico*, the official organ of the National Academy of Medicine, which condensed six months' transactions into the one issue reviewed in The Journal, Feb. 2, 1918, p. 351. An arrangement has recently been perfected with *El Universal*, a daily newspaper of the city of Mexico, which devotes one of its Saturday pages to scientific medicine, giving the official, signed report of the proceedings of the Academia Nacional de Medicina, translations of important medical articles appearing in other languages, and news of interest to the profession throughout Central and South America. This "Saturday Medical Page" is in charge of Dr. A. B. Vasconcelos, and he hopes to make it a scientific forum for the profession in Mexico and elsewhere. Some of the articles in The Journal and in the *American Journal of Diseases of Children* have already been reproduced, as also the notice sent out by the Secretary of the American Medical Association to the physicians of Mexico inviting them to be present at the annual meeting of the Association in June at Chicago.

REPORT ON PROGRESS OF TRENCH FEVER INVESTIGATIONS

TRENCH FEVER COMMISSION OF MEDICAL RESEARCH COMMITTEE, AMERICAN RED CROSS *

Majors R. P. Strong, Homer F. Swift and E. L. Opie; Captains
Ward J. MacNeal, Walter Baetjer and A. M. Pappenheimer,
M. R. C., U. S. Army, and Lieutenant A. D.
Peacock, R. A. M. C. (T.)

At the first meeting of the Medical Research Committee of the A. R. C., held in October, 1917, and presided over by Major Alexander Lambert, Chief Surgeon, American Red Cross, one of us[1] suggested the subject of the transmission of trench fever as being one of the most important for investigation in connection with the loss of man-power in some of the armies on the western front, and as being a more urgent problem for study in connection with the prevention of this disease than that of its etiology, the latter problem having already been studied extensively. It was requested that a statement be submitted at the next meeting of the committee regarding our present knowledge of this disease. This report was submitted at the meeting of the Research Committee held in November, and was published in the *Medical Bulletin* of the A. R. C. for December. Following the reading of this report it was voted that the subject of the method of transmission of the disease, and an investigation regarding the infectious properties of the blood in trench fever, were important problems for investigation, and that such investigations should be undertaken. A trench fever committee, consisting of Majors Cushing, Swift and Strong, was therefore appointed. At this and at subsequent meetings, one of us[1] was asked to plan and take charge of the work, select the personnel, and begin the experiments as soon as possible.

Major Cushing was asked (in November) to confer with the British authorities in reference to cooperation on these investigations, and to see if either the services of Mr. Bacot of the Lister Institute, or of Lieut. A. D. Peacock, R. A. M. C., could be secured to help in the work.[2] He received considerable encouragement from Col. T. R. Elliot, R. A. M. C., and Gen. Sir Wilmot Herringham later wrote inviting one of us to attend a meeting of the Medical Investigation Committee of the B. E. F., held Dec. 8, 1917. There were present at this meeting Col. Sir William Leishman, chairman, Major-Gen. Sir John Rose Bradford, Major-Gen. Sir Wilmot Herringham, and Col. W. O. Beveridge. This committee then voted to accept our offer of assistance in the study of trench fever, and after some discussion agreed to turn over to us for investigation two subjects; first, the method of transmission of the disease, and, second, the question of the infectious properties of the blood, with a view to repeating and confirming if possible the previous work of Major McNee, R. A. M. C.

It was finally arranged, on the recommendation of Gen. Sir William Macpherson, A. D. G. M. S., by Field Marshal Sir Douglas Haig, the commander-in-chief of the British armies in France, and General Pershing, the commanding general of the American Expeditionary Forces, that this work should be carried on at a stationary hospital of the B. E. F. which was near enough to the line, where cases of trench fever in the very early stages of the disease could be secured. Perhaps the most important problem was the securing of volunteers for the experiments, for, since the disease could not be transmitted to animals, it was clear that unless volunteers were secured, the experiments could not be performed. Col. M. W. Ireland, U. S. M. C., successfully undertook this task, and the commander-in-chief of our army, December 22, gave permission to General Bradley, our chief surgeon, to have these experiments made on volunteers from the American army, provided, as Colonel Ireland had outlined, that each volunteer was to have it carefully explained to him what he was volunteering for, and that after this explanation he should sign a paper that he was willing to undergo the experiment.

---

* Read by Major R. P. Strong, March 15, 1918, at the Pasteur Institute, Paris, at the meeting of the Medical Research Committee of the American Red Cross. A similar report of the scientific results was presented at the meeting of the Inter-Allied Sanitary Conference, Paris, March 13, 1918, and is preserved in the archives of that commission.

* Reprinted from the American Red Cross Medical Bulletin, March, 1918.

[1] Major Strong.

[2] The services of Lieutenant Peacock were secured, Jan. 26, 1918.

In the meantime the necessary equipment with which to carry on the work had been selected and gathered together in Paris, the funds for the purchase of the same being supplied by the A. R. C. through the instructions of Major Lambert, its chief surgeon. The laboratory apparatus and supplies, tents, lumber for latrines, ablution chambers, flooring, drainage and water pipes, window glass, etc., were shortly afterward received at the stationary hospital where the experiments were to be carried on. Sixty volunteers from the U. S. Army arrived a few days later and eight others subsequently.

The first week was occupied largely in the examination of the volunteers and in converting the empty hut supplied us into a laboratory, in erecting tents, and in building latrines, ablution chambers, construction of drains, etc., in which work we were greatly assisted by the British personnel of the hospital. Clinical histories of the volunteers were taken, physical examination made, and bacteriologic and serologic examinations of the blood, urine and feces performed, in order that complete records of the men might be available before the experiments were made. All the men used in the experiments were healthy and robust.

Four-hourly temperature charts were kept of all of them from the date of their arrival. A plan for semiweekly inspection and bath, and for complete sterilization of clothing once a week, was arranged, and other precautions were taken to prevent the men from becoming lousy by natural means during their station at this hospital. In order that the results obtained in the experiments should be unquestioned, the men of the detachment also were segregated from the B. E. F. hospital personnel and patients.

The experiments were conducted on the plan already described at a previous meeting, relating to the subjects of the transmission of the disease and of the determination as to whether the organism causing it was situated in the blood, and particularly in the blood cells, as had been previously reported.

Thirty-four men have been employed in the blood inoculation experiments, and these have been inoculated either with blood or some constituent element of it taken from trench fever cases in the febrile stage of the disease. Of these, twenty-three have developed typical trench fever. Sixteen of these were inoculated with whole blood, of which number fifteen have developed the disease. The number of individuals inoculated with whole blood may seem large, but it should be observed in this connection that in every series of the experiments it was necessary to determine at the time the presence of the virulent organism in the trench fever blood employed. Unless its presence could be demonstrated in the whole blood used at the time and under the conditions of the other experiments, no conclusions could be drawn regarding its apparent absence in any part of the blood or in filtrates of it.

Five individuals were inoculated with clear unfiltered plasma of the blood, free from cells, all of whom have contracted the disease; four were inoculated with washed corpuscles, of whom three have developed trench fever; five with plasma or serum filtered through Berkefeld filters, of whom none have contracted the disease; and two with extracts of ground corpuscles, filtered through Berkefeld filters, of whom none have contracted the disease. From these experiments it is evident that the organism causing the diesase is present in the blood and particularly in the plasma of the blood. It is also evident that it may be centrifuged down with the corpuscles of the blood and is not washed free from them by saline solution, but sometimes appears to adhere to them in sufficient quantity to produce the disease after injection of the corpuscles. The organism is perhaps also brought down by the fibrin meshwork of the clot when the clotted blood is centrifuged. From the experiments performed up to this time it would appear that the organism is either not present in the filtrates or at least is not present in sufficient amount, or in proper condition, to produce the disease following inoculation. It may remain behind or in the filter, in which case it is probably of sufficient size to be visible under the microscope under certain conditions or during some stage of its life history.

The incubation period of the disease produced by inoculation with blood varies from 5 to 20 days. Of 20 cases inoculated with whole blood or plasma: in 9 cases it was 5 days; in 4 cases, 6 days; in 2 cases, 7 days; in 1 case, 9 days; in 2 cases, 13 days; in 1 case, 19 days, and 1 case, 20 days. In those cases, with one exception, in which the incubation period was long (2 cases of 13 days and 1 of 20 days) the individuals were inoculated with blood either taken late in the disease (sixth or seventh day) or during the relapse of the fever. The blood appears from the inoculation experiments to be most infectious on the first and second days of the disease, and more infectious during the first attack than during the relapse. In the first series of inoculations the blood was taken from seven cases of trench fever occurring naturally in members of the B. E. F. and was injected from each case into a single American volunteer. All of the seven volunteers developed the disease. The organism causing the disease has in addition been carried from three trench fever cases through three more generations in man from the original case in three series of experiments.

In the inoculation experiments, varying susceptibility to the disease and relative immunity of some individuals are demonstrated by the length of the incubation period, the severity of the attack, and even, in one instance, by failure, so far, to develop trench fever. With reference to these instances of relative immunity by parallel experiments, it was shown that the organism was at the time alive and sufficiently virulent in the blood to infect other individuals in a shorter time, while the more immune individuals inoculated at the same time developed the disease later, or, in one instance, has remained healthy.

In relation to transmission of the disease by the louse *Pediculus corporis*, twenty-six men have been subjected to experiment. Of these, twenty-two have harbored lice which have bitten trench fever patients in the febrile stages of the disease, and the remainder have harbored, for the same period of time, normal, uninfected lice which have not bitten trench fever patients. Eight other volunteers living under exactly the same conditions as those contracting trench fever and kept free from lice, as well as the four controls bitten or infested by normal uninfected lice, have all remained healthy. In the great majority of the experiments the lice were pure bred and were hatched from ova brought from England.

We have previously reported the method of infection, but it may be advisable to repeat here that three groups of lice, numbering from twenty-five to 100 adult lice each, have been placed on the trench fever patients as follows:

Group 1, feeding during the first and second days of the fever.

Group 2, feeding from the third to 6th days of the fever.

Group 3, feeding for the first week of the disease.

These three groups, as they were removed from the patient with trench fever, were placed on a volunteer. In one series of experiments they were all to remain on the volunteer until he contracted trench fever or for a period of thirty or more days. In a second series of experiments one half of them were to be removed from the volunteer after from forty-eight to sixty hours from the time they had bitten the original trench fever patients, and were then to be placed on a second volunteer to remain until he developed trench fever, or, if he did not develop trench fever, for thirty days. These two series of experiments have been performed in order to exclude purely direct mechanical transmission of the blood and organism by the louse.

In another series of experiments planned, the interval between the biting of the infected patient and the second volunteer has been extended to six days.[3]

In still another series of experiments comprising three volunteers, so-called "wild lice" were employed for infection; that is, lice taken from the clothing of trench fever patients. A fourth series of experiments is being performed to see if there is hereditary transmission of the virus of trench fever in the louse.

---

[3] It was originally planned in case the louse was found to convey the infection to test its infectivity at intervals of forty-eight hours up to the limit of time of such infectivity.

In the majority of the experiments the lice have been placed in a covered cell made of calico, strapped on the arm with adhesive plaster. Into this cell is placed a small piece of flannel shirt. The cell measures inside from 3 to 4 inches long by about 2 inches wide. In it the lice live naturally, clinging to the fibrous cloth, and at other times wandering to the skin, feeding and depositing their excrement. They also breed and lay ova, some of the latter of which hatch in the cell. At intervals the cell was removed, the lice examined, and the patient, in some instances, was allowed to scratch the area if he so desired. In this way perhaps louse excrement sometimes entered slight abrasions caused by the scratching. Often a crushed louse was found in the cell, for the patient might scratch himself with the cell on his arm. In other words, if the individual contracted the disease in this manner from the louse it was evidently by a natural mode of infection. So far twelve of the individuals who have harbored the infected lice in this manner have contracted the disease. The time which elapsed from the date when the lice were first placed on these individuals to the date of the beginning of the disease has been: 1 case, 16 days; 1 case, 17 days; 2 cases, 19 days; 1 case, 20 days; 2 cases, 21 days; 1 case, 25 days; 3 cases, 26 days.[4]

The period from the time the lice were put on the patient to the date of the development of the disease, as would be expected, is somewhat longer than the incubation period in the majority of the cases in which the disease was produced by the injection of a large dose (10 c.c.) of the blood, though in two instances, as noted, the individual inoculated with whole blood did not develop the disease until about the twentieth day after inoculation.

The disease produced by inoculation of the blood or by the louse infection is apparently the same. In the four men, Nos. 23, 9, 28 and 52, who have developed the disease, it should be noted that the lice employed in infecting them were allowed to feed first on four trench fever patients. They were then after an interval placed on four different volunteers, Nos. 5, 39, 47 and 13, for approximately two days. One half of them were then removed from these men and placed on Nos. 23, 9, 28 and 52, who developed the disease after nineteen, twenty-six, twenty and twenty days, respectively. Apparently, therefore, the transmission of the disease by the louse is not necessarily direct and mechanical.

The cases of experimentally produced trench fever have been seen, and the diagnosis of the disease confirmed, not only by ourselves but also by the members of the Trench Fever Commission of the B. E. F., consisting of Sir William Leishman, chairman of the commission, Major-Gen. Sir Wilmot Herringham, Major-Gen. Sir John Rose Bradford, and Col. W. O. Beveridge, as well as by a number of other prominent clinicians.

Clinical laboratory serologic and bacteriologic examinations of blood, and of feces and urine of each patient employed and of each volunteer who has developed the disease, have also been made. The investigations and experiments have also demonstrated that trench fever is a specific disease and is not a form of typhoid fever.

They have also confirmed certain clinical knowledge of the disease. These and other points will be discussed fully in a complete report.

To summarize, it has been shown that the organism causing trench fever is present in the plasma of the blood and up to the present time it has not been shown to be filtrable (though in regard to the filtrability of the virus, sufficient time has not elapsed in the inoculated subjects for us to give a final decision). The disease is transmitted naturally by the louse *Pediculus corporis*, and apparently this is the important and common means of transmission. The experiments are still in progress and a report will be made later of further results.

---

[4] Since this report was read, transmission of the infection by the louse has been demonstrated in two more cases with incubation periods of thirty and thirty-five days, respectively.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

ANTIPNEUMOCOCCUS SERUM.—A serum obtained from horses immunized by injection of virulent pneumococci. Each lot of antipneumococcic serum is submitted by the manufacturer to the U. S. Hygienic Laboratory for potency test before it is issued.

Actions and Uses.—The value in pneumonia of the serum properly prepared and administered seems to be established. Early massive (from 50 to 100 Cc.) intravenous doses of a highly potent serum, prepared from the type of pneumococcus present in the case to be treated are necessary. Investigations indicate that the pneumococcus in lobar pneumonia may be referred to one of four types in respect to its response to serum treatment (Dochez and Gillespie, THE JOURNAL A. M. A., Sept. 6, 1913, p. 727). The serum used should be obtained from an animal immunized with pneumococci of the type corresponding to that present in the special case under treatment. Thus far Type I serum alone seems to be on reasonably secure clinical ground.

Lederle Antitoxin Laboratories, New York (Schieffelin and Co., New York).

Antipneumococcus Serum, Type I.—Marketed in a pressure syringe containing 50 Cc.

Parke, Davis and Co., Detroit.

Antipneumococcic Serum, Type I.—Marketed in a piston syringe containing 50 Cc.

E. R. Squibb and Sons, New York.

Anti-Pneumococcic Serum, Type I.—Marketed in vials containing 50 Cc.

PHENYLCINCHONINIC ACID, U. S. P. (See N. N. R., 1918, p. 269).

Acid. Phenylcinch.-Morgenstern.—A brand of phenylcinchoninic acid, U. S. P.

Manufactured by Morgenstern & Co., New York. No U. S. patent or trademark.

Tablets Acid. Phenylcinch-Morgenstern.—Each tablet contains acid. phenylcinch-Morgenstern 0.5 Gm. (7.5 grains).

Sodium Phenylcinch. Water-Morgenstern.—A solution of sodium phenylcinchoninate containing sodium bicarbonate and sweetened with sugar, representing the equivalent of 1 Gm. (15 grains) acid. phenylcinch.-Morgenstern per fluidounce. It is prepared by dissolving acid. phenylcinch.-Morgenstern 15 Gm., sodium bicarbonate 11.7 Gm., sugar 90 Gm. in water enough to make 450 Cc.

PROCAINE. — $CH_2(C_6H_4.NH_2.COO).CH_2[N(C_2H_5)_2].HCl$. The monohydrochloride of para-aminobenzoyldiethyl-aminoethanol.

Action, Uses, Dosage, Physical and Chemical Properties.—See New and Nonofficial Remedies, 1918, p. 32.

Procaine-Rector.—A brand of procaine complying with the N. N. R. standards.

Manufactured by the Rector Chemical Company, Inc., New York, under U. S. patent No. 812,554 (Feb. 13, 1906; expires 1923) by license of the U. S. Federal Trade Commission.

BARIUM SULPHATE FOR ROENTGEN-RAY WORK (See N. N. R., 1918, p. 56).

Barium Sulphate-Brady for Roentgen-Ray Work.—A brand complying with the N. N. R. standards for barium sulphate for Roentgen-ray work.

Manufactured by Geo. W. Brady &. Co., Chicago.

Health and Taxes.—Provisions and expenditures which aid in the reduction of the things which sap the vitality of the nation will aid in preventing increased taxation for the support of the growing army of the unfit.—*Public Health* (Mich.).

THE COST OF LIVING AND ADEQUATE NUTRITION

The problems of the standard of living have a bearing on the medical profession in more than one way. When the family income is reduced to a dangerously low level, the possibility of undernourishment is always present. The efficiency of the members is likely to be lowered, and sickness is almost certain to become prevalent. A vicious circle of successive misfortunes tends to become established. With the entrance of disease the already low earning capacities are impaired, so that the treatment of the afflicted must be provided and managed through public or private philanthropic agencies. The socialization of medicine makes an urgent appeal as the outcome of precisely such circumstances.

The cost of living has been discussed at times in these columns. A decade or two ago it seemed to be quite possible for an average family of five or more, living in an urban community, to maintain a fair standard of living, without incurring debt, on an income of $750 a year. Estimating an allowance of two fifths of the income for food — a liberal proportion from the economist's point of view—somewhat less than $6 a week would thus be provided to procure the minimum of wholesome food.[1] In other words, as a recent writer has expressed it, $750 was ten or fifteen years ago a large enough sum to provide a family of father, mother and from three to five young children with the necessities for the maintenance of a fair standard of living, provided the money was wisely expended. A study made some years ago in New York indicated the necessity for an allowance of at least 22 cents per person per day for food; but the studies of Stern and Spitz[2] in Boston after the outbreak of the European war disclosed that this sum was no longer adequate under the conditions of urban food prices.

Obviously the "living wage," the "standard of living" and the "working efficiency" of laboring classes, which comprise three quarters of the families in the United States, are closely interrelated. Never before has information bearing on these themes been more needed. All calculations based on conditions of a decade ago, or even those existing two years ago, leave us in the lurch. The purchasing power of money has become radically different. This may suffice to explain why so many sociological-physiologic studies in this field have been undertaken recently. One of the latest is concerned with the cost of living of working class families in Roxbury, Mass.,[3] as late as the spring of 1917 following the rise of prices during the winter of 1916-1917. Statistics actually collected led Stites to the conclusion that, without making allowance for the rise in prices of other items, and considering merely the necessity of spending more for a minimum ration, the smallest income on which a normal family could maintain a proper standard of living in a city like Boston was $850 a year — that is, reckoning fifty working weeks a year — $17 a week; and if the amount spent for food was to be a proper proportion of the total expenditures, the family income in the latter part of 1916 should have been at least $1,000. By the end of April, 1917, however, the simplest diet that would furnish adequate nourishment cost nearly $2.75 per unit per week. A family of father, mother and four small children should have spent for food at that date a sum that would amount to more than $568 a year. In order to have proper food and also to meet the other expenses of a normal existence, the family would have had to spend at least $1,100 a year. The weekly income, therefore, should have been about $22.

It is not likely that the majority of working class families are yet provided with resources of this magnitude, despite the great increase in wages in certain fields. For this reason it is interesting to learn what conditions of health and nourishment were actually observed in communities where the income was less than food prices seemed to demand. Estimation of the Roxbury budgets, says Stites, reveals the fact that at least eleven of the sixteen families were underfed. The amounts spent on food by these eleven households varied from a sum 40 per cent. short of an amount that would have purchased a living ration, to an amount only 2 per cent. short of that desirable minimum. Two families of this group spent less than two thirds of the amount that should have been at their command for food purchases, and four families had only about three quarters of the sum they needed. The average sum spent by these eleven families was about 20 per cent. less than it should have been. In not very vivid contrast to this state of affairs, the budgets of four other families show a slight excess of expenditure for food, an excess averaging about 6 per cent. more than the sum necessary to buy an adequate supply. One family out of the group of sixteen spent approximately the correct amount.

[2] Stern, Frances, and Spitz, Gertrude T.: Food for the Worker, [illegible]

[3] Stites, Sara H.: A Study of the Cost of Living of Working Class Families in Roxbury, Mass., Jour. Home Economics, 1918, 10, 147.

It requires little speculation to reach the conclusion that when income is so restricted in relation to the cost of food, the other items in the budget, such as rent, fuel, clothing and insurance, must be limited. One feature of the Roxbury inquiry cannot fail to interest the medical reader:

> Expenditures for health were very small, and it was a matter of interest to observe that no money was wasted on patent medicines. Three families spent nothing at all for the maintenance of their health during the weeks of the investigation. Most of the families, however, spent an average of a few cents a week for drugs and for treatment. Several sent their children to the Forsythe Dental Infirmary and paid small sums for the services rendered them there. One or two others availed themselves of the opportunities offered by hospital dispensaries for treatment of chronic troubles, as in the case of a child who had suffered from infantile paralysis.

The problems of maintaining those who cannot economize more is on us in new relations. Our profession is bound to meet them; and it cannot avoid contributing its share in the solution of great sociological questions.

SODIUM VERSUS POTASSIUM

The European war has taught us many lessons. Among them is the realization that we had become so dependent on Germany for certain things as to take for granted that this dependence was a necessity. Before the war, nearly all the potash used in the United States was obtained from Germany, where there were large natural deposits and, particularly, in such a form as to make them readily usable. As a result, Germany easily developed a potassium industry far ahead of that of any other nation. When the embargo was declared on Germany, the price of potassium salts in this country began to soar. This rise in price was one of the early manifestations of our previous dependence on that country for some of our important chemicals. During these years of supremacy of German potash, large natural potassium compounds were available in the United States, but not in such a form as to be easily adaptable for technical use. Nor was their chemical refinement commercially feasible against the German prices. However, since the war, American chemists have been investigating our own resources of potassium. Now the industry is developing favorably, demonstrating again that we can become independent of Germany in those instances in which necessity dictates. It will be a long time, however, before the potassium industry will be sufficiently developed to supply the urgent needs of war-time work.

Meanwhile, when a much-needed substance becomes scarce, or conditions develop making it necessary to economize in the use of a substance, we look around to see what substitute, if any, is available. In this instance we do not have to look far. Chemists tell us that potassium and sodium are sufficiently similar to be used interchangeably, and the latter is readily available. Within its borders the United States has an abundant supply of sodium salts in wells and mines, as well as in the oceans, and in forms readily usable from the commercial and the technical standpoint.

Why, then, have potassium salts become so generally used to the exclusion of many of the sodium salts? The answer has been, "German propaganda." Be this as it may, an editorial writer in a recent issue of the *Chicago Chemical Bulletin*[1] also credits it to prejudice:

> The sodium salt should be superior to the potassium salt and yet because of the prejudice which extends throughout the chemical and medical fraternity, we continue to buy an inferior article at high prices and refuse to buy a superior article at a reasonable cost. Such is custom, tradition and prejudice among men—the chemist and medical doctor seem to be no exception in this regard.

Whatever the cause, we are so accustomed to using potassium rather than sodium salts that it has become a habit with us.

In addition to the chemical similarity of potassium and sodium, there is no preponderance of evidence to warrant us in believing that potassium salts as a therapeutic agent have any advantage over sodium salts.

Economically, the sodium salts now occupy a much more favorable position than the potassium salts; for instance, the current price of potassium acetate is $2 a pound, and of sodium acetate, $0.62; potassium bicarbonate, $1.28, and sodium bicarbonate, $0.05; potassium bromid, $1.93, and sodium bromid, less than half, $0.86 a pound; potassium chlorate, $0.86, and sodium chlorate, $0.57; potassium hydroxid, $3.50, and sodium hydroxid, $1; potassium iodid, $4.64, and sodium iodid, $5.15; potassium permanganate, $5.23, and sodium permanganate, $3.50.[2]

There are three reasons why sodium should be substituted for potassium: 1. By avoiding as much as possible the use of that which goes into ammunition or other war-time channels, especially if there is a scarcity, it will help win the war. 2. Therapeutically, the sodium salts are on the whole as good as potassium salts, and in some instances better. 3. Sodium salts are much cheaper than the corresponding potassium compounds. Physicians should acquire the habit of prescribing sodium compounds in preference to potassium compounds.

Dr. Robert [illegible]

---

[1] Sodium and Potassium, Chicago Chem. Bull., May, 1918, p. 94

[2] Sodium chlorate and sodium permanganate are not offici have not been standardized. As potassium permanganate is larg for fumigation with formaldehyd, it can be replaced by other reage The higher price of sodium iodid is attributable to the fact that it has not been widely used. No doubt as soon as the demand has increased, sodium iodid will decline in price below potassium iodid.

In connection with the foregoing, it is gratifying to note that the Army has recently awarded a contract for 40,000 pounds of sodium permanganate, totaling $100,000. At previous times the Army has purchased potassium permanganate, simply, we presume, because sodium permanganate was not entered in the supply lists; this one order of sodium permanganate, thereby breaking away from the potassium habit, should save the government about $100,000.

SOME LESSONS FROM TRENCH JAUNDICE

Among numerous lessons that the war has taught the medical profession, the importance of a proper recognition of certain forms of infectious jaundice must be included. Sufficient information is now available to make it seem unjustifiable for a careful clinician to utter an offhand diagnosis of ordinary catarrhal jaundice on the basis of simple icteric symptoms unattended by pain; for trench jaundice, as it occurs among the fighting forces, has directed attention anew to the widespread prevalence of an acute infectious disease characterized by malaise, prostration, and gastro-intestinal symptoms at onset, by fever of varying degree, and by jaundice of varying intensity and duration. In severe cases, bleeding from mucous surfaces and albuminuria are common. In moderately severe cases the rather high fever, marked prostration, and absence of local signs tend to exclude local disease of the biliary tract and present the clinical picture of an acute infection. It is stated,[1] however, that light cases of this affection seem to be clinically indistinguishable from ordinary catarrhal jaundice and therefore are seldom diagnosed correctly in the absence of an outbreak of the disease, which naturally directs attention to the probably infectious character of the malady.

Since 1916, it has become increasingly more probable that acute infectious jaundice is not merely the accompaniment of some long known infection, but is due to a definite micro-organism, the *Spirochaeta icterohaemorrhagiae*. It is assuredly not an entirely new disease; for, long before the present war, acute infectious jaundice was recognized as occurring especially among troops, sewer workers, agricultural laborers working in wet soil, and in mine workers. Neill,[1] of the United States Public Health Service, has collected evidence to indicate that something comparable to what we are discussing occurred among troops in the War of 1812; even more probable are the indications of the outbreaks of a similar malady in our Civil War. Among the civil population of the United States, epidemics of jaundice closely resembling those now believed to be caused by the spirochete have occasionally appeared.

From the standpoint of an understanding of the etiology and preventive measures, the discovery of the same spirochete in wild rats at various places has been of the utmost importance.[2] The organism has been found in rats taken from the trenches where the disease had appeared among the troops, and likewise in rats captured in such widely separated localities as Washington, Nashville and New York. Noguchi has thus presented the situation:

> The finding of the causative organism of infectious jaundice among wild rats in America, and the identification of this strain with those found in Asia and Europe, seem to be particularly important in revealing a latent danger to which we have been constantly exposed, but from which we escape as long as sanitary conditions are not disturbed by untoward events.

The mode of infection is still largely problematic. One can scarcely assume that rat-bites could account for all of the numerous cases. Such observations as have already been made indicate that about 10 per cent. of all wild rats wherever located probably carry the *Spirochaeta icterohaemorrhagiae* in their kidneys and excrete them in the urine. Hence Neill[1] ventures the hypothesis that if this organism finds a favorable environment in the soil, a sufficient number may live long enough to infect a human being who gets them in the mouth or on the skin. Under these conditions a larger number of rats also take up the spirochetes. In any event, every practitioner may proceed forewarned and prepared to recognize Weil's disease, which now is entitled to the more formidable designation of spirochetosis icterohemorrhagica.

THE ROCKEFELLER FOUNDATION AND ITS MEDICAL PROJECTS

Although the Rockefeller Foundation is at present devoting by far the larger part of its available resources to the support of war work, its projects have so largely acquired medical or hygienic interest that a mention of them seems desirable. They may be classified in general as dealing with medical education on the one hand and public health problems on the other. The educational projects along medical lines are too numerous to permit detailed mention here. The establishment of medical schools and hospitals in China, the organization of a school of hygiene at Johns Hopkins University for the training of sanitarians, and the investigation of medical education and public health activities in South American countries are some of the features of work in progress.

Among the diseases, hookworm infection, malaria, yellow fever and tuberculosis have received attention from some directions. Thus last July the foundation, through the International Health Board, appointed Dr. Livingston Farrand, president of the University of Colorado, director of a commission which went abroad to undertake the task of setting up in France, in close cooperation with the French government and the medical profession, a dispensary, publicity and training demonstration which should aim at helping to control tuberculosis. The work of the International Health Board in its warfare against hookworm disease has been referred to from time to time in THE JOURNAL.[1] Efforts directed to the control of the disease were extended during the year 1917 to three of the states in Brazil, to Siam, the Fiji Islands, the Seychelles Islands, and to four additional states of the Union — Alabama, Arkansas, Georgia and Maryland.[2] In one island, Antigua, the work that had been undertaken was completed. The board was at work during the year in thirty-seven areas, which included twenty-five foreign countries and twelve American states.

[2] Noguchi, Hideyo: Spirochaeta Icterohaemorrhagiae *in* American Wild Rats, and Its Relation to Japanese and European Strains, Jour. Exper. Med., 1917, **25**, 755. Jobling, J. W., and Eggstein, A. A.: The Wild Rats of the Southern States as Carriers of Spirochaeta Icterohaemorrhagiae, The Journal A. M. A., Nov. 24, 1917, p. 1787. Neill (Note 1)

Recognizing clearly that malaria is a community problem rather than an affair of individuals, the International Health Board of the foundation has furnished demonstrations of the possibility of mosquito control. The Arkansas demonstrations are now reported as completed. At Crossett, Ark., the drainage problem was neither difficult nor expensive. The attack was therefore centered on exterminating the mosquito. The effect of this was striking. The numbers of doctors' calls for malaria fell from 600 in October, 1915, to forty-six a year later and to fourteen in October, 1917. The per capita cost for the first year was $1.24. This included a considerable amount for capital expenditure in ditching and draining. During the second year (1917) the maintenance cost fell to a much lower figure. Crossett has now assumed full control of its malaria work. At Hamburg, Ark., after a year of successful demonstration, the entire expense of maintenance is being met by the community. The principle of teaching others to help themselves cannot but be commended as sound.

The campaign, projected some time ago for 1917, to rid the world of yellow fever, has been retarded by the war. It is believed that the seed-beds of the disease have been found on the west coast of South America, in a region along the south shores of the Caribbean Sea, in a strip along the north Brazilian coast, and in a certain area on the west coast of Africa. Despite the interruptions to the plans, scouting parties are on guard. The foundation's authorities believe that the real fight against yellow fever will come when the war is over; yet it is hoped wholly to exterminate the disease from the world.

An experiment that will be watched with interest is involved in the cruises of a hospital and dispensary ship carrying medical relief to the southern islands of the Philippine group. If these peaceful visits to remote places are successful, they will serve to demonstrate that for purposes of placating primitive and suspicious peoples, medicine has some advantages over machine guns. This mode of dealing with a backward people has further general significance, to quote President Vincent, for the development of a system of mobile dispensaries operating from a base hospital. The principle may find expression equally well in a motor-car dispensary, with physician and nurse, operating through a rural area from a general hospital in an American county.

The war service rendered with the aid of the foundation's funds through the Rockefeller Institute for Medical Research are better known. To its war demonstration hospital, to the institute laboratories and to the institute hospital, medical officers of the Army and Navy are being officially sent for study and experience. To this may be added the plans to facilitate, under the direction of Major Thomas W. Salmon, the treatment of "shell shock" — the term for "that wide range of cases from true paralysis to simple cowardice." Mental diseases, subject to the investigations of the National Committee for Mental Hygiene, are not overlooked by the foundation's resources. The after-care of the victims of infantile paralysis has likewise been the recipient of aid. The many normal activities of the Rockefeller Foundation, President Vincent remarks, are not isolated items, each independent of the others; they all fall into a world-wide organization in the interests of scientific knowledge applied to human welfare.

BENEFICENT STREPTOCOCCI

The mention of the term *Streptococcus* is more than likely to bring disagreeable sensations and unpleasant recollections to the minds of those who hear it. Thoughts of abscesses and suppurative processes, of inflammation and other pathologic reactions will arise in those for whom the word has any significance at all. From the standpoint of mere terminology this should not happen; for *Streptococcus* is merely the designation of a type of micro-organisms, of cells that divide in one plane so as to form short or long chains. However, association often determines the habits of mind as well as of body. The streptococci have so long been associated with disease that even the bacteriologist will inevitably tend to retain this relationship uppermost in his mental reactions. The condemnation of this group of bacteria is not of recent origin; for the attempts to produce powerful immune serums against streptococci date back to the earliest days of immunology. The differentiation of the types, the recognition of the peculiar pathogenicity of *S. viridans, S. hemolyticus* and others, and the appreciation of their baneful elective localization have not served to lessen the dislike of these enemies of mankind and the animal races.

There are instances in which the presence of streptococci does not lead to quite such severe indictments.

---

[1] Problems in the Campaign Against the Hookworm, editorial, THE JOURNAL A. M. A., Nov. 10, 1917, p. 1611; Hookworm in the Mines of China, Nov. 17 1917, p. 1701; Hookworm Infection in Deep Gold Mines in California, Dec. 22, 1917, p. 2116.

[2] These and other facts here cited are taken from Vincent, G. E.: The Rockefeller Foundation, Review of Work in 1917, New York, 1918.

In addition to the distinctly pathogenic groups that differ among themselves in virulence there are streptococci which are common in the udder, in the saliva, and in the intestine. They are generally believed to be devoid of real virulence; but the garget, mammitis, or mastitis related to the udder of cattle, their hoof rot and navel ill cannot be mentioned without casting additional suspicion on chain bacteria. Lately the designation *Streptococcus lacticus* has been assigned to milk-souring organisms once dignified with the name *Bacterium lactis-acidi.* Whether they win approval or condemnation depends on one's attitude toward their performance. Sour milk may be a desideratum in many instances; in still others it gives the impression of undesirable spoiling.

A government dairy bacteriologist in the Bureau of Animal Industry[1] has presented streptococci in an entirely different rôle, namely, as producers of flavor substances and other ripening changes in food prepared for consumption by fermentation, and particularly in the ripening of cheese. In this connection, says Evans,[1] the streptococci are important as one of the factors concerned in rendering palatable many articles of food in use throughout the world. But they are unobtrusive and demand little attention—only that the proper conditions for their growth shall be provided. The manufacturer of the food meets this demand without knowing why; he knows simply that if he follows such and such a procedure he will obtain the desired results. Therefore the flavor-producing streptococci have escaped notice.

Evans has found that streptococci differing from the more familiar *Streptococcus lacticus* are common in ripening cheese of various kinds and in other foods, such as kefir, the mash from which the Japanese condiment "soya" is prepared, and the Chinese "toku," or soy bean cheese. All of these represent products of fermentation of some sort. Evans believes that a study of the mouth, fecal and udder types of streptococci will show that cheese streptococci belong to those familiar types. Some conception of what such organisms can accomplish is summarized in Evans' report: A cream cheese inoculated with *S. lacticus* alone has its own peculiar flavor; a cream cheese inoculated with *S. lacticus* and *Streptococcus x* has a decidedly different flavor; one inoculated with *S. lacticus* and *S. kefir* has another flavor; and when all three species of streptococci are used together, still another flavor is produced. As some people prefer their ice cream flavored with vanilla, and others like chocolate flavoring best, so the one cheese flavor is more pleasing to some people, while others prefer another. It is gratifying to know that the highly variable demands of a discriminating public can be met in some respects by the employment of suitable streptococci in a beneficent rather than a baneful way.

Current Comment

A MEDICAL ROLL OF HONOR

The survey of the war service of the medical profession, including the fundamental data relative to the supply of physicians in proportion to the population, appears in this issue of The Journal. As stated in the introduction to the survey, its compilation has been most difficult and time-consuming. Yet we believe that its importance more than justifies the work, time and expense involved in its preparation and publication. Undoubtedly it will be of great interest to every physician in the country; it will surely be of practical value to those who are directly concerned with the problem of supplying the Medical Department of the Army and Navy with a sufficient number of medical officers. While the tabular matter constitutes a survey, the list of names is, as stated, a real Honor Roll. It represents men who have made sacrifices for their country — men who have not only left the comforts of their homes, but also have given up professional work which in a majority of instances yielded far more income than the pay which they will receive as medical officers, even though they attain the highest possible rank. Among them are many of the most prominent physicians in our profession, including noted specialists, as well as surgeons and internists. This Honor Roll shows that the medical men of this country are not slackers. While the tabular matter indicates that there are only 19,692 medical officers, this does not represent the total number of physicians in military service. Including the Medical Corps and Medical Reserve Corps of the Army, the Medical Corps of the National Guard now in the Federal service, the Medical Corps of the National Army, the Medical Corps and the Medical Reserve Corps of the Navy, there are a total of 23,196 physicians actually commissioned, and practically all on active duty. Let it be remembered also that there are some 25,000 physicians engaged in the work of the local, district and advisory boards. As The Journal has stated repeatedly, the medical profession may be relied on to respond to any call the country may make on it.

LEST YOU FORGET

The authorized strength of the Regular Medical Corps of the Army is 2,975. The total present strength, i. e., on May 24, is 868. This indicates a splendid opening for over 2,000 ambitious medical men under 32 years of age.

KEEP UP YOUR OWN HONOR ROLL

Undoubtedly many of our readers would like to keep up to date a record of those—especially in their own county or state—who are giving their services to the government. This they will be able to do with little effort. Commencing this week, THE JOURNAL will publish a list, grouped by states, of those who, from this time on, accept commissions, with rank. It will be a comparatively simple matter, week by week, to copy the names into the Honor Roll as it appears in this issue of THE JOURNAL. It will take only a few minutes' time, and the satisfaction of having a complete list will be sufficient to pay for the slight effort. As noted in the introductory matter to the survey, there will be prepared for the county society and for the state association officials a list of registered physicians within the respective jurisdiction—that is, for the county or the territory covered by the component county society, and also for the state as a whole. On this list will be indicated (*a*) those who are commissioned; (*b*) those whose applications are pending, and (*c*) those who have been honorably discharged. These lists will be compiled as rapidly as possible; but not till after the meeting of the Association next month.

A MEDIEVAL PANACEA

At a period like that of the present when well-defined specialism has become an established fact in medicine and is accepted by the dependent laity as an inevitable, if not indispensable, feature of practice, the word "panacea" awakens a sequence of soothing reflections. Even the placebo is nowadays specialized for each suitable case. Little wonder that Asclepiades was looked on by the Romans as "a person sent from heaven" because the measures of treatment that this popular physician prescribed were agreeable and could at the same time easily be employed by almost any one. How can we of the twentieth century, accustomed to a multiplicity of difficult and sometimes dangerous therapeutic methods, appreciate the comfort of a medieval panacea, that which Bacon defined as a medicine by which life is protracted to its utmost natural limits, since it expels infirmity, reduces evil complexions to a good condition, and cures all diseases? Such a one Steele[1] has recently extracted, in new translation, from the Secretum Secretorum supposed to have been written by Aristotle for Alexander. The medium—a preliminary part of the prescription—consists of the juice of sweet pomegranates, apples, sugar and grape juice, mixed with that of sour pomegranates, quinces or apples, and boiled down to the consistency of honey. In the first medicine, for strengthening the brain, heart and stomach, a decoction of roses and violets was made; to this parsley water, sweet marjoram and bugloss extract were added. After further addition of myrobalans and cloves, and after standing twenty-four hours, the mixture was reduced to one third by heat. The product was completed when it was incorporated with the basal honey-like medium along with musk, ambergris and aloes. Seven equally complex concoctions are described for fortifying the stomach, strengthening the viscera, tempering the stomach to expel melancholy, or to correct the liver. The final mixture of all in one, along with fresh tamarind pulp, oil of balsam and other rare products is then subjected to what Steele has happily designated "a grand orgy of expense" in the preparation of the supreme panacea. Powdered pearls, rubies, sapphires and amethysts, emerald dust and lastly finely divided gold are incorporated in the electuary in a gold pot, incensed with aloes. The product is then exposed to the influence of the heavens for eight days, "being carefully guarded from exposure to the moon in her malignant aspects." The dose is 1 dram fasting and 1 dram after meat. Humorous, do we say? Perhaps some of our present day nostrums or even prescriptions will likewise be quoted a few centuries hence as instances of the perpetuation of quackery in all ages.

THE LITCHI NUT AS FOOD

Although the edible litchi or so-called Chinese hazelnut, *Litchi chinensis,* is by no means unknown in this country, it has never attained sufficient prominence to deserve a place out of the class of dietary novelties. Most nuts that have obtained popularity as food products in the United States are rich in protein and fat. The chestnut alone is conspicuous for its richness in starch and its freedom from oil. According to the latest experiments of Read[1] at Yale University, the litchi likewise is practically fat free and contains little, if any, protein. From the nutritive standpoint the litchi was shown to deserve consideration because of its content of carbohydrate which is a mixture of simple sugars, principally invert sugar, such as is found in honey. An added flavor is due to the presence of citric acid, with possible traces of other common fruit acids which, as Read remarks, stimulate the appetite and are prized as "thirst relieving" substances. The possibilities in the way of suitable fruits and nuts, both of which the litchi resembles in some respects, are not so varied that an added one is not worthy of respectful consideration.

LARGE CITIES DELINQUENT

An analysis of our survey, or Honor Roll as we prefer to call it, will show that the large cities have furnished the smaller percentages of physicians to the Army and the Navy medical services. Yet it is these centers of population in which fewer physicians are needed in proportion to the population. Because of accessibility, one physician can care for two or three times as many patients as can be served in rural communities. Again, availability of hospital facilities, and the fact that the public is more and more inclined to go to hospitals, tend to economy of the physician's time. Our greatest efforts to secure volunteers for the Medical Reserve Corps must be made in the cities.

THE CHICAGO SESSION

SELECTIVE SERVICE REGULATIONS AND STANDARDS OF PHYSICAL EXAMINATION

Discussion by Persons Connected with and Interested in the Selective Draft

At the Chicago session, there will be a discussion on the Selective Service Regulations and on the "Standards of Physical Examination" by persons connected with and interested in the selective draft. Meetings for this purpose will be held at the Studebaker Theater, Thursday, June 13, at 2 p. m., and Friday, June 14, at 10 a. m.

THURSDAY MEETING, 2 P. M.

Medical Aspects of the Selective Service:

Discussion opened by:

Major Hubert Work, presiding, from the Provost Marshal-General's Office.

Col. Frank Billings, from the Surgeon-General's Office.

Mr. Graham Taylor, Illinois, representing Local Boards.

Col. James Phalen, representing the cantonments.

Dr. James B. Herrick, Chicago, representing the District Boards of Appeal.

Lieut.-Col. J. S. Easby-Smith, Washington, D. C., representing Provost Marshal-General Crowder.

Voluntary five-minute addresses and inquiries will be invited. Reply to inquiries will be made by Lieutenant-Colonel Easby-Smith.

FRIDAY MEETING

8:30 a. m.—Conference: Lieut.-Col. J. S. Easby-Smith and Major Hubert Work, with medical aides to the governors.

10 a. m.—Joint Session of medical aides, medical members of Local, District and Medical Advisory Boards, and dentists. Information discussion of the Selective Service Regulations with the representatives of the Provost Marshal-General's Office.

The "Standards of Physical Examination" will be available for discussion.

CONFERENCE OF MEDICAL SCHOOLS

A conference of medical schools, under the auspices of the Council on Medical Education of the American Medical Association, will be held at the Gold Room of the Congress Hotel, Tuesday, June 11. The sessions are to begin at 9 a. m. and 2 p. m. The conference will consider war problems in medical schools. The opening address will be given by Col. William H. Welch, who will act as chairman of the conference.

The program is as follows:

Committee on Education and Special Training, General Staff of the Army:
- Lieut.-Col. Robert I. Rees, Military Aspects of Training.
- Dr. Charles R. Mann, Educational Considerations.

Medical Department of Army:
- Lieut.-Col. Horace D. Arnold, Medical Schools.
- Col. V. C. Vaughan, Medical Teachers.

Bureau of Medicine and Surgery, U. S. Navy:
- Admiral E. R. Stitt, Medical Inspector, U. S. Navy.

Medical Schools:
- President Ray Lyman Wilbur; Deans Samuel W. Lambert, J. Whitridge Williams, John M. Dodson and William S. Carter.

Council on Medical Education of the American Medical Association:
- Dr. N. P. Colwell.

Council on Medical Education, American Institute of Homeopathy:
- Dr. George Royal.

State Licensing Boards:
- Dr. Walter L. Bierring; Mr. Augustus S. Downing, and Dr. John M. Baldy.

GUESTS AT THE ANNUAL SESSION

The annual session of 1918 will be conspicuous for the distinguished guests who will honor the Association by their attendance. This session is distinctly a war session. The military medical department of our government will be represented by numerous officers, including the Surgeon-Generals of the various services. From London will come Sir Arbuthnot Lane and Sir James Mackenzie, perhaps as noted a surgeon and an internist as could be selected from among the British profession; the Canadian army will be represented by Col. Herbert Bruce. Dr. René Sand has been delegated by the Belgian general consul to represent that government. M. Justin Godart, for three years undersecretary of state for the military medical service of France, with Major E. Rist and Major Edmond Locard, will represent the French medical service. There will also probably be a representative from Australia and one from Italy; these names, however, are not yet available. Representative of the Red Cross will be Mr. J. J. O'Connor, director. The liaison officers from the Surgeon-General's Office. Col. Claude K. Morgan, C. M. G., R. A. M. C., of the British government, and Col. Charles Dercle of the French Army Medical Corps will also be present. The program of the Section on Diseases of Children includes Dr. Paul Armand de Lille of France and Dr. Truby King of New Zealand. This session will have an international character, serving to bind together more closely the bonds which are daily becoming stronger between our government and its allies.

GENERAL MEETINGS

One of the usual features of the annual session of the American Medical Association has been the President's Reception and Ball. Because such a feature would not be in accord with the times, it will be omitted this year, as it was last. However, there will be three general meetings.

Opening General Meeting

The Opening General Meeting will be held at the Auditorium Theater, Tuesday evening, June 11, at 8:15. In addition to the usual opening program, including the President's address, there will be a patriotic address by the Hon. Frank O. Lowden, Governor of Illinois. At this meeting, foreign guests will be introduced.

The War Meeting

The second general meeting will be held at the Medinah Temple, Ohio and Cass streets, at 8:15 Wednesday evening. The program for this meeting will consist of patriotic singing, and short addresses by some of the foreign guests, including those from Belgium, France, Great Britain, Canada and Australia, and, it is hoped, from Italy; by representatives of the Red Cross, of the Army and of the Navy, who have been on foreign duty, by Major-General Gorgas and by Admiral Braisted.

The Patriotic Meeting

The popular Patriotic Meeting will be held on Thursday evening at 8:15 in the Auditorium Theater. As already announced, the principal addresses will be those of Prof. John M. Coulter, on "Science and the War," of Judge Charles S. Cutting on "The Law and the War," and of Bishop C. P. Anderson on "American Ideals." The Great Lakes Training Station Band will be one of the features of this meeting. There will also be choral and other singing.

CLINICS AT THE CHICAGO SESSION

The local committee of arrangements, through its subcommittee on clinics, has provided a very complete and comprehensive schedule of clinics covering the five day period, June 6 to 11, inclusive.

No clinics will be scheduled after Tuesday, June 11; hence there will be no conflict with the regular programs of the Scientific Sections of the American Medical Association.

The preliminary announcement made in The Journal, May 11, has been added to materially, and details of all clinics will be printed and ready for distribution to those who attend. Over four hundred clinicians will participate, and the average number of clinics will exceed one hundred for each day. The list of clinicians and the hospitals in which they work, together with the hours of their clinics, has been completed and will be mailed to any physician on request. The final details of the cases are the only feature remaining to be completed; naturally there will be minor variations up to the hour of the clinics.

The committee has information as to the capacity of each amphitheater, and if the attendance demands it, admission will be by ticket, in order that no clinic may be overcrowded.

The headquarters of the clinic committee will remain at the office of the Chicago Medical Society, 25 East Washington Street, until Thursday, June 6, when the headquarters will be moved into the Sherman House and all information and tickets will be given out from there.

The schedules in the hands of the committee show that practically every specialty will be represented every day throughout the entire period.

The committee desired to repeat that there is no charge to Fellows of the American Medical Association for the privilege of attending these clinics.

Charles E. Humiston, Chairman.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 24, 1918, the personnel of the Medical Department of the Army included:

Medical Corps: 868, including 1 major-general, 65 colonels, 110 lieutenant-colonels, 298 majors and 394 lieutenants.

Medical Reserve Corps: 19,092, including 1,366 majors, 4,921 captains and 12,805 lieutenants. On active duty: 17,103, including 1,278 majors, 4,630 captains and 11,195 lieutenants.

Medical Corps, National Guard: 1,201, including 19 lieutenant-colonels, 244 majors, 153 captains and 785 lieutenants.

Medical Corps, National Army: 141, including 2 brigadier-generals, 16 colonels, 115 lieutenant-colonels and 8 majors.

The discharges to date are:

Causes	Number	
	M.R.C.	M.C.N.G.
Physical disability	664	52
Inaptitude	257	20
Other branches of the service	507	71
Resignations	119	33
Domestic troubles	59	0
Needed by community	50	0
Deaths	75	5
Dismissals	9	2
Duty completed	1	0
No reasons given	14	0
	1,755	183

To Be Brigadier-General Robert E. Noble, M. C.

On May 20 the Senate confirmed the nomination of Robert E. Noble, M. C., U. S. Army, as brigadier-general in the National Army. General Noble was born in Georgia. He graduated from the Alabama Polytechnic Institute in 1891, received his medical degree from Columbia University in 1899, and was an honor graduate of the Army Medical School in 1904. He served three years in the Philippine Islands, and for seven years was in the Canal Zone. He accompanied General Gorgas on a sanitary mission to South Africa and also renderd valuable service at Vera Cruz in 1914. When the United States entered the war he was a major in the Medical Corps and took charge of the organization and assignment of medical officers. He has also acted as director of hospitals.

Divinity and Medical Students Must Register

According to a statement by Provost-Marshal General Crowder, all medical and divinity students reaching the age of 21 on or before June 5, must register on that date along with all other young men born between June 6, 1896, and June 5, 1897. The exceptions to this rule are officers and enlisted men of the Regular Army, Navy, and Marine Corps, medical officers of the National Guard and Naval Militia, while in Federal service, members of the Officers Reserve Corps and enlisted men in the Enlisted Reserve Corps while on active duty. According to a law signed by the President on May 20, 1918, all students who were preparing for the ministry in recognized theological or divinity schools and those preparing for the practice of medicine and surgery in recognized medical schools on that date are exempt from the draft. However, they must first register in order to be exempted.

Special Board to Investigate Pneumonia

A board of medical officers, consisting of Cols. Deane C. Howard, M. C., U. S. Army; Frederick F. Russell, M. C., U. S. Army; Victor C. Vaughan, M. C., N. A.; Lieut.-Col. William H. Welch, M. C., N. A., and Contract Surg. Rufus Cole, has been appointed for the purpose of making an investigation as to the nature, causes and prevention and treatment of pneumonia, and its complications, in the various military camps in the United States. It will report from time to time to the Surgeon-General of the Army, to whom a full report will be made as soon as practicable after the completion of the investigation.

Decorated for Bravery

On May 28, it was announced that the British Military Cross for bravery had been awarded to the following officers of the Medical Reserve Corps attached to British units in France: Capt. Thomas Edward Walker, Cleveland, and Lieuts. Lynwood M. Gable, New York City; Abraham I. Haskell, Minneapolis; James B. Clinton, Philadelphia; Samuel Adams, Jersey City, N. J.; Gouverneur H. Boyer, Pottsville, Pa.; Harold E. Foster, Castile, N. Y.; John B. Gregg, Iowa City, Iowa; Albert L. Jones, Weatherford, Texas; Baldwin L. Keyes, Philadelphia; Guy D. Tibbetts, Bennington, N. H., and Harvey C. Updegrove, Easton, Pa.

INSTRUCTIONS TO MEDICAL COLLEGES

A circular letter to medical colleges issued from the Surgeon-General's Office, dated May 24, 1918, gives instructions to medical colleges as follows:

Continuous Sessions.—The circular letter urges all medical schools that can do so to hold summer sessions for the next senior class—the class of 1919—so as to enable those students to complete their course in the medical schools three or four months earlier. Medical schools which are able to establish the continuous session for the other three classes and at the same time maintain the efficiency of instruction are invited to do so. The immediate adoption of the plan, however, is left to the judgment of the individual schools.

In arranging for continuous sessions, the plan of four terms of twelve weeks each during the calendar year is favored, but the plan of three terms of sixteen weeks each is acceptable. One week in each term is allowed for examination, and the time specified means actual teaching exclusive of vacations. The college year under the "quarter" plan would thus consist of three quarters, including thirty-three weeks of actual instruction, and under the three term plan, two terms including thirty weeks of actual instruction.

Matriculation for Next Session.—A circular letter issued by the Surgeon-General's Office authorizes "well recognized" medical schools to begin matriculation of the freshman class of 1918-1919 at once, whether the next session begins this summer or in the fall. A bona fide matriculation will be accepted as establishing membership in the class, as affecting eligibility for enlistment in the Medical Enlisted Reserve Corps.

Medical Faculties.—It is planned to maintain efficient and adequate teaching forces in "well recognized" medical schools, and deans of medical schools have been asked to submit lists of essential teachers for the coming year as a basis for the selection of those who should remain as medical teachers for that period unless an extreme emergency should arise. The Surgeon-General is definitely of the opinion that a teacher of students in the Medical Enlisted Reserve Corps may render as valuable service as those on duty with the active military forces. The appropriate recognition of such services in a military way is now being given serious consideration.

Other Problems.—Other problems of medical schools will be considered at the conference to be held in Chicago, June 11, the program of which appears elsewhere in this issue of The Journal.

INTERALLIED SCIENTIFIC FOOD COMMISSION

The first meeting of this committee was held at Paris in March, and the second meeting opened, April 30, at Rome. France is represented by Prof. E. Gley, C. Langlois and J. Alquier; Great Britain by E. H. Starling; the United States by Profs. R. H. Chittenden and Graham Lusk, and Italy by Profs. F. Bottazzi and L. Pagliani. There are also delegates from the farmers, economists, statisticians, etc., of the different allied countries. The food commissioner for Italy, Senator Crespi, presided at the conference. It is planned to have a secretary representing the commission in each of the allied countries, with a central office and secretary general at Paris. In France, Wednesday, Thursday and Friday are now meatless days, except that horse meat can be sold in shops selling horse meat alone. The slaughterhouses are to be closed from Monday evening to Friday morning, and the total animals slaughtered is restricted to two-thirds of the average number in March. Similar restrictions are to be enforced in Italy, except that mutton and goat's flesh can be sold and served on Wednesdays, and there is no restriction in the sale of pig products. Three days in the week are poultryless days.

REMEDYING THE REMEDIABLE DEFECTS OF REGISTRANTS IN GROUP B—THE REMEDIABLE GROUP

From: Office of the Provost Marshal-General.
To: Draft Executives in all States.
Subject: Registrants in the Deferred Remediable Group.

1. This is to advise the Executives of the Selective Service of the increasing number of registrants anxious to enter the Army, but who have been placed in Group B (the deferred remediable group) because of physical defects which disqualify them for general military service, but which in the opinion of the Medical Examiners may be remedied by appropriate treatment, or surgical operations, not in themselves involving risk to life.

2. Requests from hospitals are also reaching this office, offering to care for registrants under treatment preparatory to their induction into service. Physicians and surgeons stand ready to cooperate with hospitals in this service.

3. Maryland through its Governor, his Adjutant-General, and Medical Aide cooperating, have already on their own motion inaugurated this patriotic cooperation, for which all parties to it volunteer. Eighty registrants from Group B (the deferred remediable group) are on the waiting list in Maryland, and it is believed that Group B registrants, in that state, will very soon be transferred to Group A.

4. No responsibility is of course assumed, either by the Government, the state, or by those called upon to perform these gratuitous services, it is to be regarded only as a patriotic commendatory measure to strengthen our soldiery.

5. You are, therefore, requested to aid, through the usual channels, in bringing to the attention of registrants the facilities available for remedying minor physical defects which, when cured, will remove the registrant from the deferred remediable group and fit him for immediate training as a soldier.

E. H. Crowder, Provost Marshal-General.
By Hubert Work, Major, M. R. C.

[Note.—There might be added to the above circular a paragraph calling the attention of physicians to this opportunity for patriotic service. During the last two or three months it has become obvious that a decided change has taken place in the attitude of registrants toward military service. Many are today anxious to get into service who previously were seeking cause for exemption; consequently many registrants placed in Group B of Class 1 for some slight physical defect, such as hernia, hemorrhoids, missing teeth, minor foot defects, or chronic appendicitis, are trying to have the defects remedied and to get into the service.—Ed.]

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending May 17, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (disease only):

All Troops	1,106.2
Divisional Camps	736.
Cantonments	1,227.2
Departmental and Other Troops	1,177.3

2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:

All Troops	39.5
Divisional Camps	33.
Cantonments	44.7
Departmental and Other Troops	38.4

3. ANNUAL DEATH RATE PER 1,000 (disease only):

All Troops	6.3
Divisional Camps	3.1
Cantonments	9.9
Departmental and Other Troops	4.2

Note: On account of frequent changes in organizations and personnel, it is no longer practicable to group troops separately as National Army, National Guard and Regular Army as has been done previously in this report. The new grouping is considered more accurate.

NEW CASES OF SPECIAL DISEASES REPORTED DURING THE WEEK ENDING MAY 17, 1918

NEWS OF THE CANTONMENTS

Camp Zachary Taylor, Lincoln Division (Eighty-Fourth), Louisville, Ky.

May 27, 1918.

CAMP HEALTH IMPROVES

Health conditions continue to improve at Camp Zachary Taylor. The death rate is going down, only four deaths being recorded at the base hospital this month. There are fewer patients at the hospital than at any time since last fall. Measles has been reduced materially, there being but forty-nine suffering from this ailment. At one time there were more than 300 cases of measles. There are less than 100 cases of mumps.

Pneumonia and empyema are declining. The latter disease was never before known to have been so prevalent as it was at army camps throughout the country during the winter. The medical officers have successfully originated methods of treatment. The mortality from this cause has been decreased and the number of complete cures increased.

PERSONAL

Major Milton Board, M. R. C., U. S. Army, has tendered his resignation to Governor Stanley as medical director for the Workmen's Compensation Board, and it has been accepted. Major Board differed with the state administration; it is said, over its policy toward the Kentucky Board of Health, and, failing to have his views accepted, he severed his official connection with the state. He remains registrar of vital statistics for Jefferson County and a major in the Medical Reserve Corps.

To Camp Jackson, Columbia, S. C., for duty, Lieut. HUGH H. HANRAHAN, Rutland.

To Camp MacArthur, Waco, Tex., as sanitary inspector, from Plattsburg Barracks, Major EDWARD A. TOBIN, North Bennington.

To Camp McClellan, Anniston, Ala., base hospital, from Williamsbridge, Lieut. RAY B. THOMAS, Enosburg.

Virginia

To Camp Custer, Battle Creek, Mich., as orthopedic surgeon, from Fort Oglethorpe, Lieut. ARTHUR HOOKS, Blackstone.

To Camp Lee, Petersburg, Va., for duty, from Fort McPherson, Lieut. LANDON E. STUBBS, Gloucester.

To Camp Sevier, Greenville, S. C., base hospital, from Camp Meade, Capt. IRA HURST, Parksley.

To Camp Sheridan, Montgomery, Ala., as assistant to camp surgeon, from West Point, Major THOMAS R. MARSHALL, Ware Neck. Base hospital, Lieut. A. NULL OSBORNE, Clinch. For duty, Lieut. BOOKER LEE, Kents Store.

To Camp Sherman, Chillicothe, Ohio, as orthopedic surgeon, from Fort Oglethorpe, Lieut. WILLIAM L. POWELL, Roanoke.

To Rockefeller Institute for instruction in bacteriology and on completion *to Army Medical School* for duty, Lieut. MARION S. FITCHETT, Cape Charles.

Washington

To Camp A. A. Humphreys, Accotink, Va., for duty, from Army Medical School, Lieut. JOHN A. BOWLES, Black Diamond.

To Camp Lewis, American Lake, Wash., base hospital, Capt. HENRY H. SLATER, Deer Park.

To Camp Wadsworth, Spartanburg, S. C., for duty, from Fort Riley, Lieut. JACOB S. SMITH, Bellingham.

West Virginia

To Camp McClellan, Anniston, Ala., base hospital, Capt. WAITMAN W. ORR, Bloomfield.

To Camp Sheridan, Montgomery, Ala., for duty, Lieut. JOHN E. CORKREAN, Cassaway.

To New York City, Bellevue Hospital, for instruction, and on completion *to his proper station,* from Camp Devens, Lieut. MILTON D. FLANARY, Charlestown.

Wisconsin

To Camp Lee, Petersburg, Va., for duty, from Army Medical School, Lieut. IRA R. SISK, Madison.

To Fort Oglethorpe for instruction, from Camp Pike, Lieut. WILLIAM W. GILLESPIE, Milwaukee.

To Hoboken, N. J., for duty, from Fort Oglethorpe, Capt. FRANK E. DARLING, Milwaukee.

Wyoming

To Charleston, S. C., for duty, from Army Medical School, Lieut. EDWARD T. GAULE, Moorcroft.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

FLORIDA

Antituberculosis Association Organized.—The Duval County Antituberculosis Association was organized at Jacksonville, May 4. Drs. William W. MacDonell, Robert H. McGinnis, Frederick J. Waas, James V. Freeman, Noble A. Upchurch, Mark B. Herlong, Joseph Y. Porter, Louis Stinson and Paul C. Perry were elected the board of directors.

Antituberculosis Activities.—At the annual meeting of the Florida Antituberculosis Association held recently in Jacksonville, a committee was appointed to formulate a state-wide policy. This includes the promotion of the organization and the maintenance of local tuberculosis associations and committees; the promotion of local public health nursing movements; local campaigns for instruction in county tuberculosis sanatoriums; public health instructions in the public schools through the "modern health crusaders"; the informing and educating of public opinion with reference to health problems, and the proper financing of this work by the use of Christmas seals and membership fees.

ILLINOIS

Held for Violation of Espionage Act.—Dr. Arthur G. Schroeder, Chicago, was arrested, May 22, on a federal warrant charged with violating the espionage act by encouraging youths of military age to evade the selective draft. He was released on bonds of $2,000.

State Society Meeting.—At the sixty-sixth annual meeting of the Illinois State Medical Society, held in Springfield, May 21 to 23, the following officers were elected: president, Dr. Edward W. Fiegenbaum, Edwardsville; president elect, Dr. J. Warren Vander Slice, Chicago; vice presidents, Drs. Harry C. Blankmeyer, Springfield, and Clara P. Seippel, Chicago; secretary, Dr. Wilbur H. Gilmore, Mount Vernon (reelected), and treasurer, Dr. A. J. Markley, Belvidere (reelected).

IOWA

Public Health Service Man Made Health Officer.—Permission has been received from the Surgeon-General of the U. S. P. H. S., to allow Dr. William C. Witte, U. S. P. H. S., to act temporarily as health officer of Des Moines until a successor to Dr. Harley L. Sayler can be appointed.

State Medical Society.—At the sixty-seventh annual meeting of the Iowa State Medical Society held in Fort Dodge, May 8 to 10, Des Moines was chosen as the place of meeting for 1919, and a war committee consisting of Drs. William W. Pearson, Des Moines; Lee W. Dean, Iowa City, and Tom B. Throckmorton, Des Moines, were appointed to coordinate the work of the medical profession. The following officers were elected: president, Dr. William L. Allen, Davenport; vice presidents, Drs. William A. Rohlf, Waverly, and Evan S. Evans, Grinnell; secretary, Dr. Tom B. Throckmorton, Des Moines (reelected); treasurer, Dr. Thomas F. Duhigg (reelected), and editor, Dr. David S. Fairchild, Clinton.

LOUISIANA

Personal.—Dr. Henry W. E. Walther has been appointed junior associate in the surgical department, urologic division of the Touro Infirmary, New Orleans.

Work of State Health Board.—The fourth biennial report of the state board of health just issued places the death rate during the biennium at 12.5 per thousand. The report calls attention to the danger from venereal disease and urges the extension of laboratory facilities for a more thorough and general examination of water and milk, and the biologic specimens submitted by physicians, and preparation and free distribution of the antityphoid vaccine. It asks an appropriation of $932,266 and an additional $50,000 for the purpose of establishing clinical and municipal hospitals in municipilities.

To Give State Board Control of Drugs.—Dr. Oscar Dowling, Shreveport, president of the Louisiana State Board of Health, and Dr. Charles A. Rosewater, chief of the narcotic clinic of Newark, N. J., who has recently made a survey of Louisiana, prepared a bill to be submitted by Senator Brown, identical with the bill recently passed in New York state, which makes the narcotic problem a health problem and places the traffic under the control of the state board of health; considers the drug addict as a sick person; encourages physicians to treat such persons; shields the addict from exploitation by incompetent and unscrupulous persons, and makes the unlawful possession of narcotic drugs and hypodermic syringes a crime.

MARYLAND

Site Chosen.—A site on the Severn s been selected for a camp for con- States General Hospital No. 2, at of Lieut.-Col. Harry S. Purnell, fficer at the hospital at Fort amed "Camp Purnell." It will onths only.

sociation.—The anniversary edical Association was held, at the Hotel Rennert, Baltimore. Dr. J. Percy Wade, of the association, presided. The other officers of zation are Drs. Samuel J. Fort, secretary, and ndry, treasurer, both of Catonsville. Lieut.-Col. rnell, commanding officer at the U. S. Army tal No. 2, Fort McHenry, was present as a ociation.

Personal.—A feature of the twelfth annual commencement of the training school for nurses at the Sheppard and Enoch Pratt Hospital, Towson, held May 22, at the institution, was the presentation to the hospital of a portrait of Dr. Edward N. Brush, physician-in-chief and superintendent. The presentation was made by Dr. William Rush Dunton, Jr., senior assistant physician, and the portrait was accepted on behalf of the hospital by Dr. Charles H. Riley, president of the board of trustees.——By the will of the late Dr. Henry M. Wilson, Baltimore, his medical books were given to the Medical and Chirurgical Faculty of Maryland.

New Quarantine Regulations.—The health department has announced that it is no longer necessary to send all smallpox patients to quarantine for care and treatment, as in the past. Those in a position to be taken care of at their homes will be permitted to remain under strict quarantine regulations and the daily surveillance of health officials. Health Commissioner Blake made the announcement as a result of a case of smallpox in a large apartment house in northwest Baltimore. The patient was quarantined in his rooms and a detail of physicians vaccinated all persons who had come in contact with him as well as others living in the building.

MICHIGAN

Service Flag Unfurled.—A service flag displaying 126 stars was unfurled at the meeting of the Wayne County Medical Society, April 8.

License Revoked.—At a special meeting of the Michigan State Board of Registration in Medicine held Jan. 23, 1918, the license of Dr. Walter Moffat, Grand Rapids, was revoked on the ground that he had been convicted in the superior court of "procuring, aiding or abetting in procuring a criminal abortion."

State Society Meeting.—At the fifty-third annual meeting of the Michigan State Medical Society held in Battle Creek, May 7, 8 and 9, under the presidency of Dr. Andrew P. Biddle, Detroit, the following officers were elected: president, Dr. Arthur M. Hume, Owosso; vice presidents, Drs. William S. Shipp, Battle Creek; Carroll E. Miller, Cadillac; John L. Chester, Emmett, and Frank W. Garber, Muskegon. On the last day, the session of the society was held at Camp Custer, where a divisional review was given in their honor.

Personal.—Dr. Christopher G. Parnell, for three years head of the health department of Jackson, has resigned to accept the superintendency of the University Hospital, Ann Arbor. ——Dr. Henry V. Tutton, Benton Harbor, was given a gold watch, chain and fob, from his boys of the Second Battalion of the Naval Militia, in appreciation of services rendered while a member of the examining board for the Navy.—— Dr. Karl Greiner, Sparta, charged with writing a seditious letter to the *Medical World*, was released from custody, May 6, as it was shown that the article was written before June 15, 1917, when the new espionage law came into effect.

MINNESOTA

Hospital Burns.—The hospital of the Oliver Iron Mining Company at [illegible] Lake was destroyed by fire, May 16; no casualties re[illegible].

Southern Minnesota Physicians to Meet.—The midsummer convention of the Southern Minnesota Medical Association will be held at Winona, June 24 and 25.

Indicted for Sedition.—The district grand jury is said to have returned an indictment, May 11, against Dr. Arthur Bremken, Pine River, charged with sedition.

Relief Society Formed.—A special committee of the Hennepin County Medical Society met in Minneapolis, May 16, to consider how the society may be of service to the families of the sixty members who have entered the Army or Navy service.

Physician Wins Verdict.—Dr. Francis E. Murphy, Aitkin, who brought suit against Ambrose Casey and Thomas Kileen for assault, was given a verdict and $11,000 damages by the jury, May 18. The plaintiff was health officer of Aitkin and was alleged to have been assaulted while placing a smallpox sign.

MISSOURI

Flag Donated to Hospital.—A large American flag donated to the State Hospital No. 4, Farmington, by Dr. William F. Kuhn, Kansas City, a former superintendent, waves daily in front of the administration building of the hospital by order of the present superintendent, Dr. Jesse L. Eaton.

Expects to Reopen Leeds Sanatorium.—Dr. Elmer J. Billick, the newly appointed health commissioner of Kansas City, assumed formal charge of his office, May 13. After an investigation of the situation, he expressed his opinion that the Leeds Sanatorium which has been in use for smallpox patients, will soon be reopened as a municipal tuberculosis hospital.

Personal.—The Shelby County Medical Society gave a banquet, May 23, at Shelbyville in honor of Dr. William Corson, who has just completed fifty years of active practice in his profession.——Dr. Hasbrouch De Lamater has been reappointed city health officer of St. Joseph.——Dr. Eugene L. Opie, St. Louis, has returned from active service in a British hospital in northern France.

A Memorial to Dr. Fitzsimon.—In memory of Lieut. William T. Fitzsimon, Kansas City, who was killed last September, when the German airplanes bombarded the Harvard University Hospital in France, the park commissioners of Kansas City have decided to erect a memorial in the form of a public drinking fountain which will bear an inscription relating the details of Dr. Fitzsimon's work and death.

Meeting of the Southeastern Association.—The southeast Missouri Medical Association held its forty-second annual meeting in Poplar Bluff, May 10, and elected the following officers: president, Dr. Alfred R. Rowe, Poplar Bluff, vice president, Dr. John H. Yount, Charleston; treasurer, Dr. William R. Goodykoontz, Caledonia; corresponding secretary, Dr. William S. Hutton, Fornfelt, and recording secretary, Dr. Will K. Statler, Oak Ridge. Charleston was selected as the next place of meeting.

State Association Meeting.—The Missouri State Medical Association held its sixty-first annual meeting in Jefferson City, May 6 to 8, and elected the following officers: president, Dr. Milton P. Overholser, Harrisonville; vice presidents, Drs. Jefferson D. Brummall, Salisbury, John C. Matthews, Springfield, T. Guy Hetherlin, Louisiana, Scott P. Child, Kansas City, and John Isbell, Washington; secretary, Dr. Edwin J. Goodwin, St. Louis (reelected); treasurer, Dr. J. Franklin Welch, Salisbury; delegates to the American Medical Association, Drs. Arthur R. McComas, Sturgeon, Franklin E. Murphy, Kansas City, and Wilson J. Ferguson, Sedalia.

MONTANA

Hospital Contract Awarded.—The contract for the construction of the Sisters Hospital, Billings, has been awarded to a Helena firm for $266,000.

Resigns After Long Service.—After thirty-one years of continuous service as physician in Fort Peck Indian Reservation, Dr. James L. Atkinson, Poplar, announces that he will resign, about July 1, and thereafter devote himself to private practice.

Society Will Protect Physicians in Military Service.—A special committee selected from members of the Montana Medical Association met in Helena, May 7, and discussed plans, whereby all districts of Montana will be sure of not being totally deprived of physicians during the time of the war.

State Nurses.—The Montana State Nurses Association met at Bozeman, April 25. Among the speakers present were Dr. James F. Blair, Bozeman, and Dr. William F. Cogswell, Helena, secretary of the state board of health. Letters were read from nurses at the front in France. Infantile paralysis was one of the topics discussed.

NEBRASKA

Hospital Notes.—Almost $13,000 has already been subscribed for the new hospital at Fall City.——Bids have been asked for the erection of a new Lutheran Hospital at Beatrice, which is to be erected north of the present building at a cost of about $125,000.

Personal.—Dr. Ernest T. Manning has been appointed health commissioner of Omaha, succeeding Dr. Ralph W. Connell, resigned.——Dr. Louis S. B. Robinson, for two years superintendent of the state tuberculosis hospital at Carney, has sent in his resignation, to take effect, June 1.——Dr. Olga F. Stastny, Omaha, has been accepted for foreign service and been notified to prepare to sail for Europe.——Dr. Artemas I. MacKinnon, Lincoln, has been appointed chief surgeon of the Orthopedic Hospital, Lincoln, succeeding Dr. Edwin C. Henry, Omaha, released to enter military service.

New State Officers.—At the fiftieth annual meeting of the Nebraska State Medical Association held in Omaha, May 6 to 8, under the presidency of Dr. Charles L. Mullins, Broken Bow, the following officers were elected: president, Col. John M. Banister, M. C., U. S. Army (retired), Omaha; vice presidents, Drs. Fred W. Buckley, Beatrice, and Artemas I. MacKinnon, Lincoln; secretary-treasurer, Dr. Joseph M. Aikin, Omaha (reelected); delegate to the American Medical Association, Dr. Joseph M. Aikin, Omaha; chairman of council, Dr. Henry J. Lehnhoff, Lincoln; secretary of council, Dr. Anders P. Overgaard, Omaha. The association will meet next year in Lincoln.

NEW HAMPSHIRE

Medical Referee Appointed.—Dr. Walter A. Bartlett, Manchester, has been appointed medical referee of the Manchester district of Hillsborough County, succeeding Dr. Maurice Watson, Manchester.

New State Officers.—At the annual meeting of the New Hampshire Medical Society held in Concord, May 15 and 16, under the presidency of Dr. George C. Wilkins, Manchester, the following officers were elected: president, Dr. Charles P. Bancroft, Concord; vice president, Dr. Augustus W. Shea, Nashua; trustee, Dr. Herbert L. Smith, Nashua; councilors, Drs. George H. Saltmarsh, Lakeport, and Frederick von Tobel, Lebanon. The orations in medicine and surgery were delivered by Drs. James J. Walsh, New York City, and John T. Bottomley, Boston.

NEW YORK

Jenkins Society Election.—The annual meeting of the Jenkins Medical Society was held at St. Joseph's Hospital, Yonkers, May 9. Dr. Edward A. Spilsbury, Yonkers, was elected president; Dr. Frank A. M. Bryant, Mount Vernon, vice president, and Dr. George B. Stanwix, Yonkers, secretary.

Tuberculosis Hospital.—Three additional counties have started work on tuberculosis hospitals under the county hospital law. The Broome County institution will be located at Chenango bridge near Binghampton, the Rockland County Hospital in the neighborhood of Summit Park near New City, and the third hospital in Nassau County near Farmingdale.

State Society Officers.—The Medical Society of the State of New York held its one hundred and twelfth annual meeting in Albany, May 20 to 22, and elected the following officers: president, Dr. Thomas H. Halsted, Syracuse; vice presidents, Drs. James F. Rooney, Albany, and Marcus B. Heyman, Suffolk; secretary, Dr. Floyd M. Crandall, New York City, and treasurer, Dr. Frank van Fleet, New York City.

Medical Women Elect Officers.—At the annual meeting of the Women's Medical Society of New York State, held in Albany, May 21, the following officers were elected: Dr. Elizabeth Burr, Thelberg, Poughkeepsie, president; Drs. Edith R. Hatch, Buffalo, and Florence Staunton, Utica, and Sara J. McNutt, New York City, vice presidents; Dr. Ethel D. Brown, secretary, and Dr. Phoebe M. B. Van Voast, New York City, treasurer.

Public Health Laboratory Association Organized.—The New York State Association of Public Health Laboratories, founded in October, 1916, held its first annual meeting at Albany, May 22. Syracuse was decided on as the place for the next meeting, and the following officers were elected: president, Dr. Warren B. Stone, Schenectady; vice president, Dr. Joseph S. Lawrence, Albany, and secretary, Dr. Howard I. Davenport, Auburn.

Sterilization Unconstitutional.—The law enacted in 1912, creating a state board of examiners with power to sterilize by operation feebleminded criminals and other defectives, has been held to be unconstitutional by Justice Rudd of the supreme court. The board of examiners created under the law examined about 200 persons and listed them as proper subjects for operation, but the attack on the constitutionality of the law has made it a dead letter since its enactment.

Personal.—Dr. Vilas G. Van Ornam has resigned as surgeon to the Semet-Solvay Company, Split Rock, to accept a similar position at a government ammunition plant at Perth Amboy, N. J.——In the city of Buffalo Dr. Douglas P. Arnold has been appointed director of infant welfare, Dr. Hugh J. McGee, medical school examiner; Dr. Nellie E. Kurtz, assistant medical school examiner; Dr. Christiana M. Greene, medical school inspector, and Dr. Albert J. Harris, assistant medical school inspector.——Dr. A. M. Cheny-Spofford has been appointed health officer of the city of Batavia, in the absence of her husband, Dr. Henry M. Spofford, who is in military service.

Medical Legislation.—At the recent session of the legislature, a number of measures of medical interest were enacted. Among them was the Sage-Adler bill creating a new state commission on the feebleminded. The commission will consist of the secretary of the state board of charities, the physical supervisor of the state charities, and a medical chairman, all of whom are to be appointed. There were also enacted a law extending the duties of the hospital development commission, and providing for the reclassification and redistribution of the inmates of the various state institutions with a view to segregation, and for the establishment of separate wards for the feebleminded; a law providing that New York City give the magistrates of the inferior courts power to remand feebleminded female delinquents for determination of their mental condition; also, measures appropriating about $3,000,000 for new construction work at institutions for the insane and feebleminded. Two new state hospitals are to be built, one at Creedmoor on the outskirts of Brooklyn, and a psychopathic hospital in New York City. Appropriations were made for all these institutions and for the site of another new state hospital in the metropolitan district, to take the place of the abandoned Mohansic institution.

New York City

Prenatal Clinic Planned.—A new prenatal clinic has been opened by the Bowling Green Neighborhood Association at its headquarters, 45 West Street, Manhattan. This is an extension of prenatal work begun at this place in 1914, by the New York Milk Committee and turned over last year to the neighborhood association.

Dairy Exhibit to Promote Use of Milk.—The Dairymen's League, during the week of May 20, conducted an exhibit in the Grand Central Palace as a part of an educational campaign to further the use of milk as a food and thus to encourage the preservation of the herds and the dairy industry in the state. A number of food experts delivered addresses and gave demonstrations designed to show the value of milk as a food.

New Home for Bronx Hospital and Dispensary.—The board of directors of the Bronx Hospital and Dispensary have purchased the property on the southwest corner of Fulton Avenue and One Hundred and Sixty-Ninth Street, consisting of three buildings and twelve city lots. Alterations will be started immediately to make these buildings suitable for hospital and dispensary purposes. When they are completed, there will be accommodations for 100 patients in the hospital.

Suits Against Physicians.—The suit for $25,000 brought by Dr. Edward W. Piper, Brooklyn, against the Brooklyn Rapid Transit Company for alleged false arrest, is said to have been decided by a jury in favor of the company, April 24.——Dr. Philip G. Becker, charged with conspiracy to violate the selective draft law by furnishing the drafted men with drugs which would cause them to be rejected, was discharged because of apparent physical unfitness. It is said that he was found not guilty, May 16.

Offer to Erect Big War Hospital.—Representatives of the Beth Israel Hospital have made a formal offer to the War and Navy departments to erect a $1,250,000 hospital on the square block bounded by Second Avenue and Livingston Place between Seventeenth and Eighteenth streets. The plans provide for the accommodation of 500 patients. Both the War and the Navy departments have taken the offer under advisement. The funds for the construction of a fifteen-story hospital building are available, and as soon as the offer is accepted, work will be begun. For several years the Beth Israel Hospital Association has intended to erect a new building, and has now hastened the plans so that it may perform a patriotic duty by turning the building over to the government for such a period of time as the latter may wish to use it.

Civil Service Examinations.—The Municipal Civil Service Commission has announced the following examinations:

Medical superintendent, Grades 4 and 5.—Application will be received until June 11. Candidates must be citizens of the United States and residents of New York state, must be licensed to practice medicine in the state of New York, and must have had at least two years' administrative service in a hospital or the equivalent. Their duty will be to assist in large hospitals under the jurisdiction of the state of New York.

Pathologic chemist.—Applicants must be at least 21 years of age, citizens of the United States, residents of New York state, must possess the degree of M.D., Ph.D., or M.S. in chemistry, and must have had at least one year of experience as pathologic chemist in a laboratory of recognized standing. Salary, $2,140.

For particulars concerning examinations, application should be made to the Municipal Civil Service Commission, New York City.

Personal.—Dr. Sophie Rabinoff is going to Palestine with the American Zionists' Medical Unit, to do child welfare work and pediatrics.——Dr. Charles H. Jaeger has been appointed assistant professor of orthopedic surgery in the College of Physicians and Surgeons in the city of New York.——Dr. S. Dana Hubbard has been appointed temporary head of the New York Board of Education, succeeding Dr. Charles F. Bolduan.——In the damage suit of Mrs. Mary Jennie Graham against Dr. Louis Jameson, in which $5,000 damages were asked, the jury, May 13, is said to have awarded Mrs. Graham $1,250.——Dr. Magnus T. Hopper, Brooklyn, has been selected as medical director of the Carson C. Peck Memorial Hospital, now being erected in Brooklyn at an expenditure of more than $240,000. The medical staff of the hospital will be headed by Dr. Bruno W. Bierbauer, and the surgical staff by Dr. William Francis Honan.——Major Eugene Wilson Caldwell is reported to be critically ill from roentgen-ray burns at his home.

Investigation of Nursing Situation.—The public health committee of the New York Academy has just made public the result of a survey of the problems relative to the shortage of nurses. The findings state that it is estimated that in military service, 10 per cent. of the soldiers are constantly sick or wounded. Of an estimated force of 2,000,000 men, 200,000 would be constantly in need of nursing services and this would require about 25,000 nurses. Up to the present time, a few more than 9,000 have been enlisted. The specific recommendations of the committee are for the enlargement of training schools in hospitals for the enrolment of women in full courses rather than to become aids, and for no lowering of nursing standards. Army training schools are discouraged. Accredited civil hospitals in cooperation with the American Red Cross should undertake the training of nurses' aids for gratuitous service only. A further recommendation urges that the employment of nurses by civilian patients be curtailed as much as possible.

OHIO

Hospital Items.—The Orchard Hospital, Marion, owned by Dr. Elmer O. Richardson, was opened, May 15.——The new general hospital, Mansfield, was opened for inspection, May 14.

Trachoma Hospital Wanted.—Members of the Hempstead Academy of Medicine, Portsmouth, are petitioning the state health department to obtain an appropriation in the next legislature to establish a federal and state trachoma hospital in Portsmouth.

Personal.—It is reported that Dr. Frank L. Sargent, Ashtabula, is seriously ill with pneumonia.——Dr. Daniel C. Brennan, Akron, who has been ill with diphtheria, is reported convalescent.——Dr. Robert H. Butler was operated on for appendicitis on board the hospital ship *Mercy,* April 30.——Dr. Edward G. Reinert, Columbus, has been appointed a member of the state board of administration.

Fines and Penalties.—It is reported that Dr. William Steele, Massillon, was charged with the illegal selling of morphin, found guilty, May 16, and fined $25 and costs for this offense, as well as $50 and costs for using the wrong registration number on prescriptions. Also, his license to buy and prescribe narcotics was revoked.——A verdict of $2,600 for alleged negligent treatment of a fractured leg, is said to have been awarded to Louis E. Shepherd, who charged malpractice against Dr. Lewis Baker, Dayton, May 8.

OKLAHOMA

Held for Helping to Evade Draft.—Dr. William E. Nichols, Tulsa, is said to have been placed under arrest, charged with furnishing drafted men with a drug which affected the eyes, and created symptoms which caused the drafted men to fail to pass the physical examination for military service. For this service he is said to have charged from $75 to $150. Dr. Nichols has been held on bonds of $10,000.

State Society Meeting.—The Oklahoma State Medical Association held its twenty-sixth annual meeting in Tulsa, May 14 to 16, under the presidency of Dr. W. Albert Cook, Tulsa. The following officers were elected: president, Dr. Leonard S. Willour, McAlester; president elect, Dr. Lewis J. Moorman, Oklahoma City; vice presidents, Drs. Edward D. James, Miami, and H. Marion Williams, Oklahoma City, and Walter Hardy, Ardmore; delegate to the American Medical Association, Dr. Mahlon A. Kelso, Enid, and Leroy Long, Oklahoma City. Muskogee was selected as the next place of meeting.

PENNSYLVANIA

Philadelphia

Medical Recruiting Office.—A recruiting station for physicians has been opened in the department of health and charities, City Hall, under Lieut. John W. West, medical examiner for the Medical Reserve Corps.

Property Purchased for War Hospital.—The buildings of the divinity school of the Protestant Episcopal Church at Fiftieth Avenue and Woodland Avenue have been sold to the Mercy Hospital, a negro institution, which will occupy the site as a hospital for negro officers and soldiers. The sale involved $120,000, and there are several buildings and 6 acres of ground. The war hospital will be directed by the Crispus Attucks Circle for War Relief, composed of leading negro physicians. The present buildings furnish accommodations for 200 beds, but it is intended ultimately to enlarge the institution to accommodate between 1,500 and 2,000 patients.

TEXAS

Personal.—Dr. Harold L. D. Kirkham has been elected secretary of the South Texas District Medical Association to serve until the annual fall meeting.——Dr. Alfred L. Ridings, Sherman, has been appointed county health officer of Grayson County.

New Society.—The physicians of Goose Creek met recently and organized a local medical society to be affiliated with the Harris County Society and elected Dr. S. P. Russell chairman, Dr. L. P. Dudley vice chairman, and Dr. Edward W. Neal Devers, secretary. The organization was named the Goose Creek Medical Society.

War Service Resolutions Voted Down.—At a special meeting of the Bexar County Medical Society, held in San Antonio, May 11, resolutions were voted down which pledged 5 per cent. of the gross monthly income of every member of the society not in the service, to a fund to be known as the "Bexar County Medical Society War Service Fund."

Public Health Association Meets.—At the annual meeting of the Texas Public Health Association, held recently in Austin, the following officers were elected: president, W. A. Bowen, Arlington; vice president, Drs. Elva A. Wright, Houston, and Beverly T. Young, San Antonio; secretary, Dr. James S. Rollings, Fort Worth, and treasurer, Dr. H. A. Wroe, Houston.

Railway Surgeons Hold Meeting.—The annual meeting of the Texas Railway Surgeons' Association was held in San Antonio, May 13, and the following officers were elected: president, Dr. William L. Brown, El Paso; vice presidents, Drs. William A. Duringer, Fort Worth; Samuel P. Cunningham, San Antonio, and Sam Webb, Dallas; secretary, Dr. William B. Thorning, Houston, and treasurer, Dr. Herschel F. Connally, Waco.

New State Association Officers.—At the fiftieth annual meeting of the State Medical Association of Texas, held in San Antonio, May 14, 15 and 16, Waco was selected as the next place for the annual meeting, and the following officers were elected: president, Dr. Selwyn P. Rice, Marlin; president elect, Dr. Robert W. Knox, Houston; vice presidents, Drs. Hugh L. Moore, Dallas; Herschel F. Connally, Waco, and Louis J. Manhoff, Aransas Pass. The councilors are Drs. Robert B. Homan, El Paso, first district; Joseph E. Dildy, Brownwood, fourth district; Cleve C. Nash, Palestine, eleventh districh (reelected); John F. Bunkley, Seymour, thirteenth district; Andrew B. Small, Dallas, fourteenth district; vice councilor for the fifth district, Dr. Thomas Dorbandt, San Antonio. The delegates to the American Medical Association are Drs. Marvin L. Graves, Galveston, and Ira C. Chase, Fort Worth, and the alternates, Drs. Edward H. Cary, Dallas, and John H. Florence, Houston. Dr. John S. Turner, Dallas, was reelected trustee.

WASHINGTON

Physician Interned.—Dr. John Reitz, Tacoma, is reported to have been interned in Fort Lawton as an alien enemy.

Money for Health Campaign.—The common council of Tacoma has passed an ordinance appropriating $5,000 from the general fund to pay special expenses of the health department.

Tri-State Meeting.—A meeting of the physicians of Washington, Oregon and Idaho will be held in Seattle, July 17 to 19. The Oregon and Idaho state associations will not hold separate meetings this year.

Personal.—Dr. W. Marvin Munsell, Grand View, has been appointed district surgeon of the Union Pacific system, covering that portion of the ground between Kennewick and Yakima.——Major James B. Eagleson, M. R. C., U. S. Army, Seattle, was a guest of honor at the meeting of the state club, Seattle, April 3. Major Eagleson is now on duty at Base Hospital No. 50, Palo Alto, Calif.——Dr. J. H. McDonald, Tacoma, underwent an operation at St. Joseph's Hospital in that city, April 6.——Dr. J. Mason Adams has returned to Seattle invalided after two years of service with the Canadian expeditionary forces in France.

WISCONSIN

Sanitary Department Organized.—Major Daniel S. McArthur, LaCrosse, acting under orders from the adjutant general of the state, has begun the organization of a sanitary department for the Wisconsin State Guard.

Wisconsin Surgeons Hold Meeting.—At the annual meeting of the Wisconsin Surgical Association held in Milwaukee, May 8 and 9, under the presidency of Dr. Horace M. Brown, Milwaukee, the following officers were elected: president, Dr. John F. Pember, Janesville; vice president, Dr. Dennis J. Hayes, Milwaukee; secretary-treasurer, Dr. Daniel Hopkinson, Milwaukee; regent, Dr. Horace M. Brown, Milwaukee, and vice regent, Dr. John van R. Lyman, Eau Claire.

Hospital News.—St. Mary's Hospital, Ladysmith, was open for public inspection, May 30. The building is three stories and basement in height, in the southwest corner of Ladysmith, on an eminence near the river.——The cornerstone for the Ashland General Hospital was laid, May 12, with impressive ceremonies. The principal address was given by Dr. John M. Dodd.——The addition to St. Joseph's Hospital has been completed at a cost of more than $20,000 and is now occupied. The addition is 93 by 37 feet, and it is three stories in height and fireproof.——Dr. Charles S. Hayman and Jonathan C. Betz have purchased an interest in the Brookside Hospital, Boscobel. Dr. Edward H. Spiegelberg retains his interest in the institution.

Personal.—Dr. Charles O. Thienhaus, Milwaukee, who was ordered to be interned during the period of the war, because as an enemy alien he had gone outside the prescribed area, has been taken to Fort Oglethorpe, Ga., for internment.——Dr. Everett W. Maechtle, West Allis, was operated on for appendicitis in a hospital in Milwaukee, May 16.——Dr. Oscar Lotz, secretary of the Milwaukee County Medical Society, was presented with a silver tray, May 14, in appreciation of his services.——Dr. Lawrence H. Prince has resigned as medical supervisor of the public schools in Madison, to become superintendent of the state school for dependent and crippled children at Sparta, where he succeeds Dr. John F. Brown, who has gone to Kankakee, Ill., to accept the presidency of the Re-Use Knitted Gauze Company.——Dr. A. T. Rasmussen, LaCrosse, was operated on recently in Milwaukee for appendicitis.——Dr. Conrad W. Wilkowske, Chippewa Falls, is reported to be ill with pneumonia at Camp Upton, L. I.——Dr. Henry T. Brogan has been appointed health commissioner of Milwaukee.

CANADA

Queen's University Graduates.—Twenty-six medical students were graduated from the medical department of Queen's University, Kingston, Ont., May 22. The medal in medicine was won by Albyn A. Cauley, Lombardy, Ont., and the medal in surgery by Henry C. Connell, B.A., Kingston.

Personal.—Lieut.-Col. F. E. Birdsall, M.D., has taken over the command of the Kingston (Ont.) Military District.——Lieut.-Col. Kenneth D. Panton, Vancouver, B. C., who went to France with one of the earliest Canadian contingents and served in Flanders and Greece, has returned to England, where he has been given the command of the Canadian hospital at Eastbourne.——Lieut.-Col. Alexander J. MacKenzie, Toronto, after prolonged service overseas, has returned home. He has been ordered to Halifax to take over military matters in that region.——Major B. M. Luton, St. Thomas, Ont., a winner of the military cross, returned from overseas recently, and has been appointed commanding officer of the new military hospital at Fredericton, N. B.——Drs. Robert J. McMilland and Andrew D. Moorhead, Toronto, who went overseas about a year ago, are engaged in a military hospital at Havre, France.——It is understood that Lieut.-Col. Harold C. Parsons, Toronto, who went overseas three years ago with the University of Toronto Base Hospital, will soon return to

Canada and become a member of the hospitals inspection committee. Capt. William Goldie, Toronto, has obtained a year's leave of absence from the University of Toronto, and will take Dr. Parsons' place in the hospital at Basingstoke. ——Dr. Alfred Thompson, Dawson, formerly superintendent of the Canadian Hospitals Commission, has again been returned as member of Parliament for the Yukon.——Dr. Frederick W. Luney, London, Ont., of the institute of public health, has been appointed pathologist of the Victoria Hospital in that city. Dr. W. F. Hodgetts has been placed on the active staff of the hospital, replacing Dr. Everett Young, who has gone to the Byron Sanatorium, and Dr. Freel, who has gone overseas.——There is great satisfaction in Canada at the announcement that Dr. Henri S. Béland, M..P., formerly postmaster-general of Canada, has been released as a prisoner of war in Germany. Dr. Beland had just been married to a Belgian woman when war broke out, and entered the Belgian Army Medical Corps. Subsequently, while he was in prison, his wife died, and he was refused attendance at her bedside. Her death was not told him until some days after her interment.——Dr. J. P. McCullough, Belleville, ophthalmic and aural surgeon to the British forces from 1915 to 1917, has opened an office in Toronto.

GENERAL

War Educational Meeting.—The National Education Association will meet this year in Pittsburgh from June 29 to July 6. The program, which has been sent out, shows that the papers and addresses will have a distinct bearing on the war.

Mail for the Expeditionary Forces.—The Postoffice Department authorizes the announcement that the Postmaster-General and the Secretary of War have agreed that mail for the American expeditionary forces in France shall be handled by the War Department.

More Army Nurses Needed.—On account of the urgent need of nurses for the Army and Navy, the American Red Cross will open a campaign, June 10, to recruit 25,000 registered nurses. The requirements for this service are that applicants must be at least 21 years of age, graduates of a recognized school for nurses and must have had at least two years of training in a general hospital. In states where registration is provided for by law, applicants must be registered.

War Hospital Problems.—A conference on war-time hospital problems will be held under the auspices of the war service committee of the American Hospital Association at the New York Academy of Medicine, New York City, June 3, at 10:30 a. m. Dr. Sigismund S. Goldwater is chairman of the committee. The tentative program will include discussions of income and expenditures, medical and surgical supplies, new constructions, labor supplies, medical and nursing service, the care of government patients, federal vocational boards, and the war risk insurance bureau.

FOREIGN

War-Time Economies.—The *Practitioner* reaches us this month with much less than its usual number of pages, but the type used has been reduced in size to correspond, so that it actually contains nearly as much reading matter as before. This has been done to meet the requirements of the government in regard to economy in paper.

Deaths in the Profession Abroad.—Lieut.-Col. **H. Stewart** of Dublin, aged 37, killed in action.——**G. Elliston**, for nineteen years financial secretary and business manager of the British Medical Association, aged 46.——**V. H. Starr**, surgeon in charge of the mission hospital at Peshawar, India, aged 35, was fatally stabbed by a fanatic, March 17.——**J. M. Clarke**, professor of pathology at the University of Bristol, aged 58.——**H. Macnaughton-Jones**, aged 73, professor of obstetrics at the University of Cork until he removed to London in 1883, where he occupied a prominent position in obstetrics and gynecologic work. He was honorary president of several of the international medical congresses of his specialty and president of the British section at the Petrograd international congress. Some of his works, notably those on diseases of women, have passed through many editions.——**E. Mosny**, lecturer on clinical medicine at the University of Paris and an authority on bacteriology and public hygiene, president of the Société de médecine publique et de génie sanitaire, aged 57. With Brouardel and Chantemesse he aided in publishing the Traité d'Hygiène, a twenty volume work.

MEXICO, CENTRAL AND SOUTH AMERICA

English and French in Medical Curriculum in Mexico.—The dean of the medical department of the Universidad Nacional of Mexico has recently inaugurated courses in English and French as part of the medical curriculum.

Personal.—Dr. F. Ocaranza, professor of physiology at the Facultad de Medicina of the Universidad Nacional, Mexico, has been appointed secretary of the Facultad. He is at the same time secretary of the Academia de Medicina.——Dr. D. Orvañanos has been appointed inspector of laboratories in the Facultad de Medicina.——Dr. A. A. da Matta of Manaos, Brazil, was recently elected foreign corresponding member of the Academia. At meeting, Dr. J. C. Urueña presented a case of pityriasis rubra pilaris, the third that has been reported in Mexico, and Dr. E. Landa, a case of abdominal round cell sarcoma with metastasis.——Dr. R. Carrillo has been engaged by the *Universal*, a City of Mexico daily, to examine systematically the health of all its employees and give such treatment as may be needed.

LONDON LETTER

London, May 7, 1918.

The Medical Examination of the Older Recruits

Under the recent military service act, medical boards will be called on to determine the physical fitness of men between the ages of 18 and 50 years, and in a few cases 55. In the case of the older men, between 43 and 50, now brought under medical review for the first time, the application of the accepted standards will require special care, and the following instructions have been issued by the government:

Grade 1. The older men will be placed in Grade 1 if they possess the full normal physical fitness to be expected of their age. Such men must not have any serious physical defect and must not suffer from progressive organic disease. They must be able to endure physical exertion involving a considerable degree of strain, and to undergo gradual physical training in order to fit them for military duty. The physical training for the older men in this grade will be carried out under special medical supervision.

Grade 2. The older men fit for Grade 2 will possess the normal physical fitness of their age. They must not suffer from progressive organic disease, and the physical defects that prevent such men from being placed in the higher grade must not be of such a nature as to diminish seriously their physical activity. They must be able to undergo a considerable degree of physical exertion of a nature not involving severe strain.

Grade 3. In this grade will be placed older men with marked physical disabilities or who show evidence of disease which is not active nor of a progressive character at the time of the examination. Although not fit to undergo military training, they may be called on to perform duty in military establishments under conditions approximating to their home life and surroundings.

Grade 4. In this grade will be placed those older men whose physical disabilities, owing to defects or progressive disease, are of such a nature as to render them totally and permanently unfit for any form of military service. The attention of the boards will, therefore, be especially given to the forms of physical disability which may become evident in the fifth decade, such as cardiovascular defects and emphysema. It is expected, however, that considerable numbers of men of this age will be found fit for military service, especially of the less arduous type.

Subject to military exigencies, the corps to which the War Office proposes to post older men are: (*a*) Combatant service: Home defense infantry, and garrison battalions at home and abroad. Royal field artillery, and royal garrison artillery at home. (*b*) Auxiliary service at home and abroad, such as Royal Army Medical Corps, Army Service Corps, as motor and horse transport, remounts and supplies; Army Ordnance Corps; Army Veterinary Corps; inland water transport and dock; railway troops; roads, and quarries. Such men will also be posted to the air force for duty with the squadrons.

Attack on Hospital Ship by German Submarine

It has now been proved conclusively that the British Hospital Ship *Guildford Castle* was attacked by a German submarine in the Bristol Channel on the afternoon of March 10, struck by a torpedo, and had a narrow escape from being sunk. At the time of the attack, 5:35 p. m., the *Guildford Castle*, which was carrying 438 wounded soldiers, was flying a Red Cross flag of the largest size, her navigating lights were also showing, and the distinctive marks denoting the character of the ship were properly illuminated. No excuse can be put forward that these distinctive marks were in any way obscured by climatic conditions, for the weather was clear, with visibility of about 5 miles, and the ship, standing well out of the water, could be plainly distinguished as a British Red Cross hospital vessel. An official inquiry into the circumstances of the attack shows that two torpedoes were fired. The first passed close to the ship's stern from port to starboard. A minute afterward a second torpedo was fired and struck the ship a heavy, sharp blow on the port side abreast of the mainmast, causing her to vibrate considerably fore and aft. Happily the torpedo did not explode. The discipline on board the ship was excellent. There was no panic, and the patients were conducted to the boats very quickly. On arriving in port the vessel was drydocked, and expert examination of the hull proved that the ship was struck by a torpedo which did not explode. The torpedo apparently rebounded after first striking the vessel, and, returning, bumped along the ship's side until it was finally struck by one of the propellers, as one of the propeller blades was found to be marked and slightly bent. An examination of the marks on the hull of the ship showed that they were not compatible with the vessel's having struck a submarine or the submarine's having come into collision with the ship.

In view of the fact that the Germans sometimes deny that they have attacked hospital ships that have been sunk, the following admission is interesting. April 24, the German official message sent out through the wireless stations attempting to confute Sir Eric Geddes' statement in Parliament on mercantile losses contained this passage: "Lloyd George and Geddes falsify the losses of ships plying in the military service, ignoring so-called naval losses, auxiliary cruisers, guardships, hospital ships, and very probably also troop transports and munition steamers—that is to say, precisely that shipping space which is particularly exposed to and attacked by the U-boats."

Outbreak of Infective Ophthalmoplegia

A considerable number of cases of acute illness marked by ophthalmoplegia and other symptoms suggestive of botulism have occurred in London and in various parts of the country. It may be remembered that the form of food poisoning described in 1895 by van Ermengem under the name botulism (*botulus*, a sausage) were due to eating sausage or fish infected with the *Bacillus botulinus*, an anaerobic organism. The outstanding features of the cases are acute onset of incomplete double third nerve paralysis, with ptosis and diplopia. Pyrexia has been present in the majority of cases and delirium in some. The source of infection is obscure. In some, no food taken by the patients was under suspicion. In others, the condition has followed eating sardines or canned salmon. In the fatal cases, the length of the illness has varied from ten days to six weeks. Pathologic investigation is not yet complete. Sections of the medulla have shown infiltration with lymphocytes and chromatolysis of the cells of the basal nuclei. Thus far the *Bacillus botulinus* has not been identified. The chief medical officer of the Local Government Board has asked physicians to obtain specimens of suspected foods and communicate with the local health officers. In one case a gas-producing anaerobic gram-positive bacillus which so far resembles the *Bacillus botulinus* has been found. Possibly the outbreak may be connected with the greater consumption of canned foods under war conditions.

Scientific Report of War Bread

The bread now in use is prepared from grain milled to 90 per cent. with the addition of other cereals. After investigation, a committee of the Royal Society has issued a report on the following questions: 1. What gain, if any, in food value accrues from a rise in the milling standard from 80 to 90 per cent., and does the dilution of wheat flour with other cereals modify the food value of the bread? 2. What would be the effect on the health of the consumption of such breads? 3. How far would such breads prove acceptable? Experiments were made with wheat flour, extracted to 80 and to 90 per cent. The analytic work was done in the biochemical department of the University of Cambridge and in the Physiological Laboratories of the universities of Glasgow and London. The diet consisted of 800 gm. of bread with butter, cheese, minced or potted meat, fruit jelly, milk and sugar, tea or coffee, and in one case beer was taken as a beverage. This dietary yielded about 3,680 calories a day. The effects were remarkably uniform. Bread made from the 80 per cent. flour yielded for nutrition 96.1 per cent. of the energy contained in the diet; bread made from 90 per cent. flour, 94.5 per cent. The loss of energy with the second bread was greater (5.5 per cent.) than with the first (3.9 per cent.). The intestinal secretions were considered to contribute largely to this. The feces with the 90 per cent. bread were more bulky, and the coarser particles of this bread produced a greater stimulation of the secretion of the intestine. The increase in the bulk of the evacuation is not an evil. and in the case of many is even an advantage. As to the nitrogenous constituents, the average digestibility was 89.4 per cent. in bread made from flour extracted to 80 per cent., and 87.3 per cent. in that extracted to 90 per cent. In most of the cases there was a slight gain in body weight with both breads. Thus a greater proportion of the energy of the grain is available for human consumption when flour is milled at the 90 per cent. scale than on the 80 per cent. scale. The increase would extend the cereal supply of energy for the country for more than a month. Against this is to be set the loss of protein in the offal as food for pigs. Another set of experiments were made with bread made from flour consisting four fifths of wheat extracted at 80 per cent., and one fifth of maize. At first the flavor of the maize was commented on, and there was in some cases disturbance of digestion, attended sometimes with diarrhea, and more often with constipation; but these symytoms passed off. The general conclusion is that bread made with the addition of maize flour was as digestible as bread made without it, and it was well digested by children. The addition of maize made practically no difference in the utilization of energy and nitrogen. Observations were made at a canteen on the dietetic effect and on the palatability of bread made from flour containing four fifths of wheat extracted to 90 per cent., and one fifth of other permitted cereals (10 per cent. barley, made up to 20 per cent. with maize and rice, or rice alone). It was found to be palatable and never to cause indigestion.

Vital Statistics for 1916

The registrar-general's seventy-ninth annual report for the year 1916, which has just been published, is of unusual interest, because in that year the war existed long enough to affect the figures considerably. The birth rate was 20.9 per thousand living, and was the lowest on record. It was 4.6 below the average for the ten years 1905-1914 (which were practically unaffected by the war). On the whole, the reduction of natality, which amounted to about 12 per cent. on the figures for 1914, is less than might have been expected, and compares favorably with the experience of other belligerent countries. The civilian death rate was 14.4 per thousand living, and was slightly below the average of the decennium before the war. The rate of 1916 is considered to be the lowest recorded, provided allowance is made for the effect of enlistment on the population. The standardized mortality of males ordinarily exceeds that of females. Up to 1860 the excess was not more than 9 per cent.; but in 1916, in consequence of the war, the excess amounted to 32 per cent. The most remarkable feature is the low death rate in the first quinquennium of life. It was much lower than any previously recorded, and was less than half the rate prevailing in the concluding years of the last century. The all-age mortality from typhoid and from scarlet fever was the lowest on record, while diphtheria and influenza were more fatal than the average. But the death rate from tuberculosis showed a further advance on the high rate of 1915, although the increase did not extend to young children, the mortality under 5 years being the lowest hitherto recorded. Cancer was more fatal in 1916 than in any other year, and cerebrospinal fever continued to be abnormally destructive.

In view of the loss of life in the war the statistics of childhood are of unusual importance. The births in England and Wales in 1916 were in the proportion of 1,049 males to 1,000 females, against 1,033 to 1,000 in the preceding five years. This proportion is by far the highest recorded during the last half century. It certainly bears out the old view, regarded by some as a superstition, that war increases the proportion of male births because Nature endeavors to compensate for the loss of male life in warfare. Of the deaths at all ages, 41.1 per cent. were those of infants under the age of 1 year. These deaths correspond to a mortality rate of 91 per thousand births, the lowest ever recorded. It was below the average in the preceding decennium by 20 per cent. This decline was in part due to low diarrheal fatality, but the greater part of it is accounted for under other diseases less subject to climatic influences. The mortality in infants from tuberculosis was 2.39 per thousand births, much the low[illegible] on record.

PARIS LETTER

Paris, April 25, 1918.

Surgery of Wounded Nerves

At a recent meeting of the Société de chirurgie de Paris, Dr. Delagenière of Mans presented an interesting communication on the remote result of the surgical treatment of wounded nerves, comparing nerve suture, grafting and liberations from fibrous constrictions.

NERVE SUTURE AND GRAFTING

Among 245 cases followed for two and a half years, there have been 181 sutures in good condition with 120 excellent results, 41 fair or mediocre (slow regeneration, but defective and incomplete), and only 20 failures, a total of 88 per cent. positive results and about 70 per cent. excellent results. He asserted that a properly made suture is nearly always successful. The earlier the suture is done, the more rapid is the regeneration of the nerve; if the suture is done late, the regeneration is retarded. Delagenière has obtained excellent results even when operating as late as twenty-eight months after nerve division. Regeneration also seemed to take place more rapidly in cases of complete division with persistent fibrous tissue than when there was solution of continuity, because then the disorganization of the peripheral segment was greater. The nerves which regenerate best are the radial, musculocutaneous and external popliteal. The internal popliteal, the cubital and especially the median, regenerate more slowly, which is perhaps due to the considerable number of sensitive fibers which enter into the make-up of these nerves, and to the danger of deviation of the regenerated nerve fibers, the motor fibers going uselessly astray in the empty sheaths of the sensory fibers, and vice versa. When there is loss of much nerve tissue, success may be had by resorting to grafting, using a piece of the musculocutaneous nerve. Of nine cases noted by Delagenière, three were almost complete and six were more or less complete successes.

It is difficult to foretell the time when regeneration will occur because a number of factors must be taken into consideration. In the case of the radial, Delagenière has often seen complete regeneration occur as early as after four months, when the suture had been done early and under the best conditions; on the other hand, in the cases of the same nerve, when conditions were not so favorable, thirteen months and more had elapsed before regeneration had taken place. The length of nerve to be regenerated must always be taken into consideration.

NEUROLYSIS: LIBERATION OF THE NERVE

It is always much more difficult to form an opinion as to the value of nerve liberation. Delagenière has done comparatively few of these operations (113); it has seemed to him that the procedure does not, as a rule, yield results superior to nonintervention. Here, nevertheless, are the conclusions which he believes may be drawn: In cases of nerve lesions of the type of a simple paralysis and in cases of constriction by a fibrous band, liberation, when done early enough, always yields remarkable results, rapid and complete. In the cases of severe and extensive compression, signs of regeneration, until then absent, will appear after a free liberation. In the complex lesions, with neuromas and *chéloides nerveuses*, liberation is wholly ineffectual; Delagenière has many times changed his plan and performed a successful suture after such a liberation. In the neuritic cases with pain symptoms (causalgia), he has had some good results follow liberation, but, on the whole, very rarely; in nearly all the cases the liberation proved a failure.

On the contrary, emboldened by the almost constant success following nerve suture, he has for the past eighteen months, in cases of severe neuritis (seventeen cases) almost constantly divided and sutured the nerve. This technic has yielded excellent results.

Wounds of Vessels

At one of the recent meetings of the Société de chirurgie de Paris, Dr. Hartmann reported a series of observations made by Dr. Gatellier in 123 cases of ligation of blood vessels, including various arteries. Of this number, twenty ligations were made for ordinary lesions, not causing shock from hemorrhage. All terminated in a cure. In the remaining 103 cases, shock was present. Among these were ninety-six cures (eight following secondary amputation) and seven deaths. So far as amputations are concerned, it must be noted that the outcome of a vessel injury depends on the artery involved. Following the ligation of a vessel of the arm, the popliteal artery and the posterior tibial vessels, the circulation is always reestablished without untoward incident; but in the case of other vessels the result is not always the same. Among five ligations of the axillary artery there were three secondary amputations (66 per cent.); in two cases of ligation of the iliac there was one amputation (50 per cent.); among eighteen femoral ligations there were three amputations (23 per cent.); among eleven ligations of the posterior tibial vessels there were two amputations (18 per cent.).

LIMITATIONS OF LIGATIONS

From these observations the conclusion may be drawn that a ligation which saves life does not always save the member. Therefore, Gatellier decided to improve on ligation. The opportunity soon presented itself in the case of a man who had received a wound high up in the popliteal space with ischemia of the leg and in imminent danger of rapidly occurring gangrene. In this case Gatellier had recourse to arterial intubation and obtained a reestablishment of the circulation in four hours.

Paralysis from Injury of Spinal Cord Without Lesion of the Dura

Dr. Georges Guillain, assistant professor à la Faculté de Médecine de Paris, and Dr. J.-A. Barré recently read a paper on this subject before the Société médicale des hôpitaux de Paris in which they showed that, independently of the cases in which a projectile of war injured the cord directly after having opened the dura mater, organic paraplegias of various types and various degrees of gravity are seen, from injury of the spinal cord from the mere passage of a projectile at a certain distance from the cord without even having injured the dura mater. He saw a considerable number of such cases during the offensive of the Somme; the mild cases had been evacuated to the interior, but he regretted to report that there were fifteen deaths. In these fatal cases vertebrae had been injured. There was either fracture of a spinous process at its base, or of a lamina, or the body of the vertebrae had been pierced. The most common medullary lesion was hematomyelia, either alone or accompanied by acute necrosis or myelomalacia. The bloody effusion was sometimes limited to parts of one or two medullary segments, and sometimes involved six, eight or even ten segments. In several cases there was a bloody perimedullary or subarachnoid suffusion and an intradural or extradural hemorrhage. Sometimes, probably following an intradural hemorrhage, a loose meningomedullary symphysis, of slight extent, had developed.

SYMPTOMS FROM CONCUSSION OF SPINAL CORD

The clinical picture of these various lesions was, in the main, of two types: (1) that of a total section of the cord (four cases); (2) that of a localized medullary lesion (eleven cases). The syndrome of a total section was characterized by the following symptoms: complete loss of motion and sensation of every kind, often loss of muscle tone, but sometimes normal at the beginning; abolition of the tendon reflexes; cutaneous plantar reflex in flexion with or without diffuse reactions; superficial cremasteric reflex often abolished at first but appearing after an attempt to induce the deep cremasteric reflex; cutaneous abdominal reflexes abolished; absence of *réflexes de défense* produced by pinching the skin of the back of the foot or by the maneuver of Pierre Marie-Foix; constant retention of the urine; disturbance of the temperature of the paralyzed members, and early or late bed-sores. Slight involuntary movements, almost continuous, of the toes were noted twice. These four patients survived for from three to five days.

The localized lesions manifested themselves by a paraplegia less uniform than that seen in the cases of total section; the tendon reflexes were abolished ten times in the eleven cases; the cutaneous plantar reflex was of a variable type, in extension, in flexion, or abolished, or different on the two sides, or transforming flexion into extension; as a rule, the cremasteric reflexes were present; the abdominal skin reflex was usually very weak or absent; the *réflexes de défense* were present in more than half of the cases. Sensation was conserved in a zone of variable height, particularly in the region of the sacral nerves. Syringomyelic dissociation, which would be expected in the cases where hematomyelia is the principal lesion, occurred seldom and was doubtful. The maneuver of Lasègue was painful, even when there was extensive or total anesthesia of the legs; it is important to note this fact, because it alone is sufficient to show that the section is incomplete. Urine retention was the rule. These patients survived longer than did those who sustained a total section of the spinal cord; they all lived more than two months.

Guillain and Barré called attention to the fact that none of the patients who had a local lesion and who had died in their service had presented the syndrome of Brown-Séquard; they have been able to evacuate all the cases presenting the Brown-Séquard syndrome and many of them have been ameliorated. This difference in gravity between the lesions, even extensive, when they remain unilateral, and the bilateral lesions should be borne in mind.

Traumatic Shock

At a recent meeting of the Société de chirurgie de Paris, Dr. R. Picqué read a very interesting paper on this subject. On the basis of personal experience, he is convinced that immediate shock is a rare occurrence, aside from rapidly fatal hemorrhage, severe concussions and certain cases of poisoning with carbon monoxid generated in the sudden combustion of the explosives, to which not enough attention has been directed. As a matter of fact, shock is observed less often at the advanced posts than at the ambulances, and less often on the firing line than at the advanced posts. Shock is due mainly to hemorrhage and to subacute infection, particularly among the victims of many wounds. Therefore, from the standpoint of treatment, the intervention in the shock cases must be active; however, no more should be done than is consistent with getting good results. The technic followed by Picqué is as follows:

During the preparation of the patient, a combination of warming, serotherapy and the administration of cardiovascular tonics, his case is investigated thoroughly in order to catalog the nature of his injuries and determine the gravity of his case, both immediate and ultimate, and outline the treatment to be adopted. The examination of the bloodvessels is of first importance. This done, the intervention is proceeded with variously according as the patient has only a single wound or multiple wounds.

TREATMENT OF SINGLE WOUNDS

In the first instance, it is a question of a conservative intervention, done rapidly, according to the technic in general use today. But, whether after shock a primary suture should be done will depend on whether the surgeon will have time to make a satisfactory excision of the contused tissues, or the reconstructing of the normal anatomy of the region will prolong an operation which should, under the shock circumstances, be of short duration. In cases of excision, rather than perform in the traumatized area an atypical operation liable to leave behind it an infection, Picqué always carries his dissection back to the healthy zone, immediately above the lesion, and amputates, after careful ligation of the principal vessels, under ethyl chlorid anesthesia. Having excised the traumatized tissue, the principal source of shock, transfusion is done if the blood pressure does not rise after a few hours. Or the donor might be prepared for the transfusion during the operating, if hemorrhage is so severe as to cast some doubt on the prognosis.

TREATMENT OF MULTIPLE WOUNDS

With multiple wounds, he distinguishes between the wounded presenting some predominant lesion and those who do not. In the former, the principal lesion should be operated on rapidly, while the accessory lesions, dissected and cleaned, are thoroughly disinfected with the expectation of doing a more complete operation later on. When the lesions are all on the same member, a careful analysis should be made to determine whether the intervention should be a conservative one or amputation. In the former case, intervention, necessarily, will be much more delicate, more laborious and prolonged than with excision. It requires the extraction of all projectiles, dissecting out rapidly all the tracts and antiseptisizing provisionally. And then, good results may be obtained from the use of cytophylactics and antiseptics. While in the strict sense of the word, these do not kill all the bacteria, they will, at least, attenuate the virulence of the bacteria for a sufficient length of time to permit of an increase of the patient's resistance, and permit a more thorough operation later. Blood transfusion does not, however, appear to be indicated in these cases.

SHOCK

Professor Quénu reported to the society Dr. Lacoste's experiences with 13 severely wounded soldiers, the injuries being limited to one member, who had all been treated by immediate amputation, within two to five hours, without a single fatality. These cases comprised 8 with a crushed leg; 2 with a crushed foot; 2 with crushed arm or elbow; and the hand had been torn off in one case. Thirteen amputations were done, 6 of the leg, 1 of the thigh, 2 of the knee, 1 Symes', 2 of the arm and 1 of the forearm. All these men were evacuated in good condition after a variable delay. All had had hemorrhage, but in spite of the anemia and bad general condition the operation was well supported. Therefore, Lacoste has come to agree with Quénu that a severe hemorrhage is not a contraindication to rapid amputation when this can be done early, and it is realized that there is no possible chance of conserving the member.

NATURE OF SHOCK

Lacoste's observations demonstrate anew the rarity of immediate shock even among cases with severe hemorrhages. Shock does not manifest itself until later, after several hours. Of course, its appearance is favored by the hemorrhage, and the existence of hemorrhagic shock cannot be denied, but usually it is of other origin. It is not a vasomotor inhibition, as has been claimed by some; still less a subacute infection, but a genuine chemical intoxication, of which it presents the entire set of symptoms. The intoxication takes its origin in the contused wounds involving large masses of muscle. Quénu admits that the crushing of a large mass of muscle liberates numerous protein substances, some of which are very toxic to the organism. The rapid disappearance of the shock following on the removal of the traumatic focus, favors the theory that the real cause of shock is located in that focus. On the other hand, the primary reunion, always aimed at and sometimes obtained, is good evidence that there had not been complete microbic evolution in the focus, and that the symptoms there must have been the result of chemical and not of bacterial intoxication.

Dr. Potherat's personal observations also confirm the rarity of immediate shock, as stated by Dr. Quénu. Having been in active service with an ambulance during a battle at the beginning of the war, there passed through his hands and those of his aids in the course of a few hours 600 recently wounded, none of whom presented shock phenomena, although a considerable number were severely wounded. Some of them had arm injuries of such extent that only a flesh or skin flap held the member attached; a cut of the scissors freed the member. Others had a leg crushed, with vast destruction of tissue; the blood flowed so abundantly that it could be collected in a basin placed on the litter carrying the wounded. But, in spite of all this, these wounded were not in a state of shock.

Marriages

Lieut. Walter Edward Foley, M. R. C., U. S. Army, Davenport, Iowa, now stationed at Camp Hancock, Ga., to Miss Ina Mary Gleason of South Haven, Mich., in Chicago, May 20.

Lieut. Stuart Howard Bowman, M. R. C., U. S. Army, Maquoketa, Iowa, now on duty at Camp Meade, Md., to Miss Bessie C. Moses of Auburn, N. Y., May 16.

Lieut. John Vardyman Dillman, M. R. C., U. S. Army, to Miss Luella Caroline Goodenough, both of Louisville, Ill., April 25.

Lieut. L. J. Schermerhorn, M. R. C., U. S. Army, Stockton Calif., to Miss Eugenia Burns of San Jose, Calif., April 28.

Lieut. John Francis Barton, M. R. C., U. S. Army, to Miss Sandra Olson, both of Calumet, Mich., May 11.

P. A. Surg. Reginald Buchanan Henry, U. S. Navy, to Miss Jane Byrd Ruffin, at Norfolk, Va., April 30.

Charles Mills Herold, Nitra, W. Va., to Miss Myra Boughton of Elyria, Ohio, May 7.

Eugene W. Mitchell, Salem, Ohio, to Miss Gladys Hildebrand of Louisville, Ky., May 15.

B. Q. Dysart to Miss Minnie B. Munnis, both of Granville, Ill., May 18.

Deaths

Major James Chew Johnston, M. R. C., U. S. Army, New York City; New York University, New York City, 1892; aged 48; a Fellow of the American Medical Association; a member of the American Dermatological Association; assistant professor of clinical medicine in Cornell University; pathologist to the New York Skin and Cancer Hospital; editor of the *Journal of Cutaneous and Genito-Urinary Diseases* from 1896 to 1902; dermatologist to the Cornell Dispensary; who suffered a general physical breakdown by reason of overwork, while on duty with a base hospital in France and was invalided home; died at his home, May 11.

Carl G. Viehe, Evansville, Ind.; New York Homeopathic Medical College, New York City, 1895; aged 48; a Fellow of the American Medical Association; surgeon to the Deaconess Hospital, Evansville; for several years president of the board of health of Evansville; while on his return from a trip to the Hawaiian Islands, was seized with an infection of the ear, followed by meningitis, from which he died in San Francisco, May 16. He was an officer of the Evansville City National Bank, and vice president of the O. H. Klamer Furniture Company.

Sylvester Demarest, Suffern, N. Y.; Bellevue Hospital Medical College, 1885; aged 56; a Fellow of the American Medical Association, and a member of the Erie Railroad Surgeons' Association; while driving in his automobile from Paterson, N. J., to Suffern, was struck by a train at a grade crossing at Glenrock, May 9, and died a few hours later from his injuries in the General Hospital, Paterson, N. J.

Stafford Potter Jones, Marinette, Wis.; Northwestern University Medical School, 1868; aged 74; a pioneer practitioner of Marinette; for many years health officer of the city; died at his home, May 11, from pernicious anemia. On April 23, the physicians of the city celebrated the fiftieth anniversary of Dr. Jones' practice in Marinette at St. Joseph's Hospital where the guest of honor was at that time a patient.

James Glasgow Heading, Port Royal, Pa.; College of Physicians and Surgeons, Baltimore, 1882; aged 58; a Fellow of the American Medical Association; director of the First National Bank of New Bloomfield, Pa.; who had been under treatment in a hospital in Philadelphia on account of disease of the kidney; died in that institution, May 13, after a surgical operation.

John Calvin Workman, Ordway, Colo.; Columbus (Ohio) Medical College, 1879; aged 62; formerly a member of the Colorado State Medical Society; at one time president of the Belmont County (Ohio) Medical Society, and president of the Crowley County Medical Society in 1914 and 1916; died in Rocky Ford, Colo., April 29, from nephritis.

Frederick Cecil Skinner, La Claire, Iowa; State University of Iowa, College of Homeopathic Medicine, 1898; aged 44; a member of the Iowa State Medical Society; who was in New York taking a special course in diseases of the eye, ear, nose and throat; died in the Post-Graduate Hospital, New York City, May 11, after a surgical operation.

Wylie Hamilton Forsythe, Louisville, Ky.; Hospital College of Medicine, Louisville, Ky., 1898; aged 44; formerly a Fellow of the American Medical Association; a member of the Kentucky State Medical Association; for several years a medical missionary in Korea; died at the home of his mother in Louisville, May 9, from sprue.

George W. Kugler, Hightstown, N. J.; Jefferson Medical College, 1885; aged 55; for many years a member of the medical staff of the Pennsylvania Railroad; died at his home, May 11, from the effects of a gunshot wound of the head, believed to have been self-inflicted, with suicidal intent, while despondent on account of ill health.

Martin Joseph Fleming, Brooklyn; College of Physicians and Surgeons in the City of New York, 1872; aged 71; formerly a Fellow of the American Medical Association; for several years a member of the visiting staff of Bellevue Hospital; a well known connoisseur of violins; died at his home, May 9, from influenza.

David Charles Davies, Pasadena, Calif.; Northwestern University, Medical School, Chicago, 1881; aged 84; formerly a member of the Medical Society of the State of California; at one time in the United States Consular service at Swanset, South Wales; died at his home, May 13.

Henry David Siegfried, Denver, Ill.; Keokuk (Iowa) Medical College, 1898; aged 46; formerly a Fellow of the American Medical Association; while in an altercation with a tenant, May 3, was struck with a club, fracturing the skull, and died from his injuries a few hours later in Blessing Hospital, Quincy, Ill.

Roger Martin, Worsham, Va.; College of Physicians and Surgeons, Baltimore, 1887; aged 56; formerly a Fellow of the American Medical Association; a member of the Medical Society of Virginia; who had been suffering for ten years from Landry's paralysis; died at Vulcan, Va., about May 6, from pneumonia.

A. A. Surg. Alan B. Cleborne, U. S. P. H. S., Savannah, Ga.; University of Virginia, Charlottesville, 1902; aged 39; formerly a member of the Medical Association of Georgia; on duty at the United States Marine Hospital, Savannah; died in that institution, May 13, while performing a surgical operation.

James Hardin Wood, Attalla, Ala.; Vanderbilt University, Nashville, Tenn., 1882; aged 60; a Fellow of the American Medical Association; president of the Etowah County Medical Society in 1914; local surgeon of the Southern and Alabama Great Southern railways; died at his home, in February.

Milan Daniel Baker, Norfolk, Neb.; University of Nebraska, College of Medicine, Omaha, 1903; aged 41; a member of the Nebraska State Medical Association; formerly coroner of Madison County; a veteran of the war with Spain; died at his home, April 27.

Horace S. Bowers, Neosho, Mo.; Kansas City (Mo.) Medical College, 1895; aged 51; a member of the Missouri State Medical Association and for many years secretary of the Newton County Medical Society; died at his home, February 23, from cerebral hemorrhage.

William Constantine Goodell, Philadelphia, University of Pennsylvania, Philadelphia, 1895; aged 55; a member of the Medical Society of the State of Pennsylvania; a specialist in obstetrics; died in the Orthopedic Hospital, Philadelphia, May 15, from heart disease.

Arthur Z. Barfield, Westhoff, Texas; Baylor University, Dallas, Texas, 1910; aged 38; formerly a Fellow of the American Medical Association; a member of the State Medical Association of Texas; died in a sanatorium at Cuero, May 8, from pneumonia.

Henry Edward Goddard, Brockton, Mass.; Dartmouth Medical School, Hanover, N. H., 1897; aged 65; a Fellow of the American Medical Association; owner and director of the Goddard Hospital, Brockton; died in that institution, May 12, from pneumonia.

Charles E. Gaines, Covington, Ohio; University of Louisville, Ky., 1894; aged 58; a member of the Ohio State Medical Association; for two terms coroner of Miami County; died in Grant Hospital, Columbus, Ohio, May 11, from diabetes.

George H. Morrill, St. Louis; Homeopathic Hospital College, Cleveland, 1861; aged 76; for many years a member of the staff of the St. Louis Children's Hospital; died at his home, April 26, from septicemia due to an infection of the neck.

Eugene M. Bishop, Wilkesville, Ohio; Starling Medical College, Columbus, Ohio, 1900; aged 42; a member of the Ohio State Medical Association; was found dead from heart disease, May 9, on the road between Hawk and Wilkesville.

Everett Amos Graves, Coatesville, Pa.; University of Pennsylvania, 1900; aged 42; a Fellow of the American Medical Association; visiting physician to the Coatesville Hospital; died at his home, April 28, from valvular heart disease.

Jean Isabelle Best Moore, Washington, Pa.; Womans' Medical College of Pennsylvania, Philadelphia, 1901; aged 41; formerly a medical missionary in Cairo, Egypt; died at the Washington City Hospital, April 7, from pneumonia.

Orestes Morton Brown, Everett, Mass.; University of Vermont, Burlington, 1883; aged 62; formerly a Fellow of the American Medical Association; a member of the Massachusetts Medical Society; died at his home, May 13.

William G. Drake, Bolivar, Mo.; Washington University, St. Louis, 1877; aged 73; a member of the Missouri State Medical Association; a veteran of the Civil War; died at his home, May 19, from chronic interstitial nephritis.

William Henry Hoag, Manhasset, N. Y.; College of Physicians and Surgeons in the City of New York, 1865; aged 78; major-surgeon of the 134th New York Volunteer Infantry during the Civil War; died at his home, May 13.

Joseph Tatum White, Freeport, Ill.; Missouri Medical College, St. Louis, 1888; aged 51; a Fellow of the American

Medical Association, and president of the Stephenson County Medical Society; died at his home, May 14, from lobar pneumonia.

William Selman Jenkins, Allentown, Pa.; Jefferson Medical College, 1890; aged 56; a Fellow of the American Medical Association; while on a fishing trip to Pocono Lake, died suddenly, May 11, from acute gastritis.

Bernard Samuel Jacobson, Baltimore; University of Maryland, Baltimore, 1916; aged 24; resident physician at the Hebrew Hospital and Asylum, Baltimore; died, May 16, from lymphosarcoma of the mediastinum.

Ephraim Morrison, Newton, N. J.; Bellevue Hospital Medical College, 1875; aged 65; a Fellow of the American Medical Association; president of the Merchants' National Bank, Newton; died at his home, May 11.

Wallace R. Flower, Ashtabula, Ohio; Western Reserve University, Medical Department, Cleveland, 1875; aged 66; died in St. Vincent's Hospital, Cleveland, about May 2, from carcinoma of liver and stomach.

William Aaron Gibson Agricola, Glascock, Ga.; University of Georgia, Augusta, 1874; aged 66; formerly a member of the Georgia Legislature; died in Sandersville, Ga., March 27, from disease of the kidney.

William Percy Gibbes, Frogmore, S. C.; Medical College of the State of South Carolina, Charleston, 1893; aged 64; formerly a member of the South Carolina Medical Association; died at his home, May 14.

William T. Speaker, Manson, Iowa; Northwestern University Medical School, Chicago, 1878; aged 66; a Fellow of the American Medical Association; died at his home, May 2, from carcinoma of the viscera.

Benjamin Franklin Wilson, Carbon, Texas (license, Judicial District Board, Texas, 1893); aged 51; a practitioner since 1891; a Fellow of the American Medical Association; died at his home, April 2.

William N. Porteous, Minneapolis; McGill University, Montreal, 1884; L.R.C.P. (Edin.), 1884; aged 62; a specialist on diseases of the nose and throat; died in Eitel Hospital, Minneapolis, May 15.

William L. Wallace, Kingstree, S. C.; Baltimore Medical College, 1883; aged 84; formerly a member of the South Carolina Medical Association; a Confederate veteran; died at his home, May 13.

Robert Hamilton Devine, Wahpeton, N. D.; Jefferson Medical College, 1897; aged 55; a member of the North Dakota State Medical Association; died at his home, May 4, from pneumonia.

Prather Buchanan Curlin, Hickman, Ky.; University of Louisville, Ky., 1902; aged 38; a member of the Kentucky State Medical Association; died at his home, May 18, from pneumonia.

Jacob A. Schneider, Concordia, Mo.; University Medical College, Kansas City, Mo., 1894; aged 62; died in the Research Hospital, Kansas City, April 4, from diabetes mellitus.

John A. Hutson, Bremen, Ga.; Atlanta (Ga.) Medical College, 1892; aged 54; formerly a member of the Medical Association of Georgia; died at his home, May 1, from heart disease.

Everett W. Gee, Richmond, Va.; Medical College of Virginia, Richmond, 1889; aged 52; a Fellow of the American Medical Association; died at his home, May 6, from heart disease.

Edgar B. Jones, Columbus, Ohio; College of Physicians and Surgeons, Baltimore, 1881; aged 62; formerly a Fellow of the American Medical Association; died at his home, May 3.

John Hardy Page, Baker, Ore.; Berkshire Medical College, Pittsfield, Mass., 1865; aged 80; a veteran of the Civil War; died at the home of a friend, April 30, from heart disease.

John Thomas Whitlock, Mount Vernon, Ill.; Missouri Medical College, St. Louis, 1890; aged 57; a Fellow of the American Medical Association; died at his home, April 30.

George G. Mallett, Caldwell, Ohio (license, Ohio, 1896); aged 55; a member of the Ohio State Medical Association; died at his home, April 26, from organic heart disease.

William Wakefield, Lake Benton, Minn.; University of Michigan, Ann Arbor, 1882; aged 72; was instantly killed, April 28, by being struck by a train at Lake Benton.

James Hickerson, Ronda, N. C.; Jefferson Medical College, 1856; aged 86; surgeon of U. S. Volunteers during the Civil War; died at his home, April 6, from senile debility.

Irene Robinson Pratt, Chicago; University of Illinois, College of Physicians and Surgeons, Chicago, 1901; aged 54; died at her home, May 15, following an operation.

Louis Frederick Frank, Milwaukee; New York University, New York City, 1879; aged 61; president of the Wisconsin Conservatory of Music; died at his home, May 12.

John Wesley Young, Richmond, Va. (license, Oklahoma, 1910); aged 53; formerly a practitioner of Lawton, Okla.; died in Richmond, March 6, from tuberculosis.

Solon Snethen Duggan, Eagleville, Tenn.; Vanderbilt University, Medical Department, Nashville, Tenn., 1884; aged 69; died at his home, May 5, from arteriosclerosis.

Rufus Lafayette Grogan, Murray, Ky.; Medical Department of the University of Tennessee, Nashville, 1895; aged 81; died at his home, May 4, from senile debility.

William Townsend Philips, Library, Pa.; University of Michigan, Medical School, Ann Arbor, 1884; aged 75; veteran of the Civil War; died at his home, May 2.

Jesse Langtry Black, Pittsburgh; Jefferson Medical College, Philadelphia, 1896; aged 51; a Fellow of the American Medical Association; died at his home, May 2.

Daniel W. Mudge, Leslie, Mich.; Hahnemann Medical College and Hospital, Chicago, 1881; aged 67; died at his home, April 29, from sarcoma of the intestines.

Eliab W. Capron, Lotus, Fla.; Albany (N. Y.) Medical College, 1855; aged 91; formerly a practitioner of Lansingburg, N. Y.; died at his home, May 2.

John A. Walls, Richmond, Ind.; Physio-Medical College of Indiana, Indianapolis, 1884; aged 69; died at his home, May 12, from cerebral hemorrhage.

Alfred William Linden Jackson, New York City; New York University, New York City, 1897; aged 56; died at his home, May 12, from septicemia.

Truman C. Campbell, Fairmont, Okla.; Beaumont Hospital Medical College, St. Louis, 1891; aged 67; died near Eva, Okla., April 12, from paralysis.

William J. McAlpin, Gurdon, Ark. (license, Arkansas, 1903); aged 82; a veteran of the Civil War; died at his home, April 21, from pneumonia.

Joseph Oliver Greenlaw, Artesia, N. M.; University of Nashville, Tenn., 1904; aged 44; died in New Orleans, February 27, from empyema.

Gilbert Daniel Furbee, Terra Alta, W. Va.; Maryland Medical College, Baltimore, 1905; aged 38; died at his home, May 3, from nephritis.

Jens Paulus Immanuel Pfeiffer, Bedford, Mass. (license, Massachusetts, years of practice); aged 76; died at his home, May 3, from paralysis.

Amasa Frank Lombard, Salt Lake City; University of Vermont College of Medicine, Burlington, 1885; aged 64; died at his home, May 1.

Aubrey J. Richardson, Pasadena, Calif.; Hahnemann Medical College and Hospital, Philadelphia, 1882; aged 58; died at his home, May 5.

Ion Marion Pfouts, Rittman, Ohio; Ohio Medical University, Columbus, 1898; aged 43; died at his home, April 23, from pneumonia.

James R. Claunch, Jonesboro, Ark. (license, Eclectic State Medical Board of Arkansas, 1903); aged 85; died, April 3, from paralysis.

Lynn B. Moore, Cotton Plant, Ark.; University of Louisville, Ky., 1881; died at his home, April 24, from cerebral hemorrhage.

John Fretts Detweiler, Uniontown, Pa.; Rush Medical College, Chicago, 1891; aged 57; died at his home, May 2, from pneumonia.

William H. Stover, Walkerville, Mich. (license, Ohio, 1896); aged 77; a veteran of the Civil War; died at his home, April 27.

C. E. Taylor, Cochran, Ga.; Louisville (Ky.) Medical College, 1876; aged 66; also a druggist; died at his home, May 8.

Francis Naulteus, Hastings, Neb.; University of Louisville (Ky.) Medical Department, 1894; died at his home, May 8.

Henry J. Parker, Clayton, Ill.; Missouri Medical College, St. Louis, 1870; aged 72; died at his home, May 6.

Freeman E. Wilson, Hanover, Mich.; University of Michigan, Ann Arbor, 1900; died, about March, 1918.

James H. McDonald, Puyallup, Wash.; American Medical College, St. Louis, 1877; aged 77; died, April 28.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

MISBRANDED NOSTRUMS

Dr. Swan's Liver & Kidney Remedy.—The National Remedy Company of New York City manufactured a nostrum called "Dr. Swan's Liver & Kidney Remedy." This was analyzed by the federal chemists who reported that it contained about 5 per cent. alcohol, over 32 per cent. sugar, more than 8 per cent. glycerin with smaller amounts of sodium salicylate, strychnin and some laxative plant drug, together with indications of juniper. It was sold under claims that led the purchaser to believe that it was an effective remedy for diseases arising from a disordered condition of the liver, stomach and bowels, for dyspepsia, female diseases and malaria and for the cure of diseases of the kidneys, stone in the bladder, etc. The federal authorities held that these claims were recklessly and wantonly false and fraudulent. The company pleaded guilty and was fined $25.—[*Notice of Judgment No. 4754.*]

Stuart's Calcium Wafers.—F. A. Stuart Co., Inc., Marshall, Mich., shipped in interstate commerce quantities of a nostrum labeled "Stuart's Calcium Wafers." Some of the claims made for the product were:

> ". . . the preparation is perfectly harmless."
>
> "Children may take it with freedom and their delicate organisms thrive with its use."
>
> "Containing no poisonous ingredients."
>
> "A perfectly safe remedy."
>
> "It can be safely used by any person, man, woman or child with the assurance that no possible injury can result from its use."

These claims with others were declared false and misleading, in that Stuart's Calcium Wafers were not harmless but "did contain a poisonous ingredient, to wit, strychnin." In addition, certain curative claims were made for the stuff, among which were:

> "For Eruptions Scrofula . . . Constipation Humor Liver troubles . . . And all disorders and symptoms arising from impure blood."
>
> "The most powerful blood purifier known."
>
> "Skin diseases are relieved when the blood is charged with this great eradicator."
>
> "Will infuse renewed energy and strength into the exhausted nerves."
>
> "Containing in concentrated form all the elements to repair nerve tissue and depleted blood."

These claims and others of similar tenor were declared by the federal authorities false and fraudulent in that "Stuart's Calcium Wafers" were "incapable of producing the curative and therapeutic effects claimed therefor." As no one appeared to claim the property, the court entered judgment of condemnation and forfeiture and ordered that it should be destroyed.—[*Notices of Judgment Nos. 4773, 4774, 4775 and 4782.*]

Turpentine Man's, or Tydings' Remedy.—Charles Tydings and Edith Tydings, copartners who did business under the firm name of Charles Tydings & Co., Ocala, Fla., shipped in interstate commerce a quantity of "Turpentine Man's or Tydings' Remedy." This preparation, according to the federal chemists, was a glucose sirup containing potassium iodid, alcohol, and traces of salicylic acid, phosphates, calcium and an alkaloid. The claims made that it would eradicate cancerous growths and cure salt rheum, catarrh, female diseases, etc., were declared false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity. Misbranding was further alleged because the quantity or proportion of the alcohol in the nostrum was not declared on the label. The concern pleaded guilty and was fined $5 and costs.—[*Notice of Judgment No. 4832.*]

Henry's Red Gum Compound.—This preparation was made by Henry L. McNulty, Norwood, N. Y. Government chemists reported that, in addition to large amounts of sugar and glycerin, the preparation also contained alcohol, chloroform and heroin. It was declared misbranded, first, because it failed to bear a statement on the label of the carton of the amounts of chloroform, heroin or alcohol in it; second, because the name was false and misleading in that it indicated to purchasers that the principal and active ingredient was red gum, a harmless medicinal agent, when in fact it did not contain red gum as its principal ingredient, but did contain heroin and chloroform, dangerous or habit-forming drugs. In addition, the government charged that the therapeutic claims made to the effect that it would cure all throat and lung diseases, croup, bronchitis, pneumonia and asthma were recklessly and wantonly false and fraudulent. McNulty pleaded guilty and was fined $25.—[*Notice of Judgment No. 4831.*]

Athlophoros.—This product of the Athlophoros Co. was analyzed by government chemists and reported to consist essentially of a solution of glycerin, sodium salicylate, oil of cinnamon and water. The preparation was sold under the claim that it was an effective remedy for sciatica, gout and sick headache, "cleansing the liver and kidneys from irritating substances," that it was a cure for neuralgia and a specific for sick headache. These claims the government held were false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity. The company fought the case and attempted to prove by means of testimonials and "expert witnesses" that their claims were not fraudulent or false. The judge in summing up the case pointed out to the jury that as the concern was charged with making "false and fraudulent" claims, it was necessary not only that the government prove that "the so-called remedy is absolutely worthless as to its curative or therapeutic effect upon the ailments for which it is claimed" but also it must satisfy the jury beyond a reasonable doubt that the company had made these statements knowingly with a "wrongful motive for the purpose of deception." Evidently the government did both as the jury returned a verdict of guilty. The concern was fined $25 and costs.—[*Notice of Judgment No. 4834.*]

Dr. Thacher's Cholera Mixture and Dr. Thacher's Amber Injection.—These preparations were sold by the Thacher Medicine Co. of Chattanooga. The "Cholera Mixture" was found to contain alcohol and morphin, in addition to a laxative drug, sugar and aromatics. It was declared misbranded because the correct amount of alcohol present was not stated on the label and it was falsely and fraudulently claimed to be an effective remedy for all cases of cholera, diarrhea, dysentery, etc., and as a remedy for ailments of teething children.

The "Amber Injection" was found to contain alcohol, opium and zinc sulphate to which acetic acid had been added. Apparently, the composition of this stuff varied, as examination of two samples showed different results. In neither case did the label bear the statement regarding the quantity or proportion of opium and alcohol as the law requires. Furthermore, it was falsely and fraudulently claimed that the stuff was a cure for gonorrhea, gleet, spermatorrhea, whites, etc. The company was fined $75 and costs.—[*Notice of Judgment No. 4838.*]

Abbott Bros. Rheumatic Remedy.—This nostrum sold by Abbott Bros. Co., Chicago, contained 24 per cent. alcohol with 5 grains potassium iodid to each teaspoonful together with extracts of drugs such as sarsaparilla and dandelion. It was sold under the false and fraudulent claims that it was an effective remedy for rheumatism of every form and stage, for sciatica, for all "uric acid troubles" and for eczema and as a cure for sciatica, gonorrheal rheumatism, inflammatory rheumatism and Bright's disease. The jury, after due deliberation, declared the concern guilty and a fine of $200 and costs was imposed.—[*Notice of Judgment No. 4842.*]

Correspondence

"VISUAL FACTORS IN EQUILIBRATION, ESPECIALLY AVIATION"

To the Editor:—In The Journal, April 13, 1918, in an editorial entitled "The Bárány Tests in the Examination of Aviators," you apparently set the seal of "editorial" approval to what seems to be a misrepresentation of the object and value of the Bárány tests in the examination of prospective aviators for the United States Army. The editorial was apparently based on conclusions drawn from several contributions which have recently appeared in medical literature; two of them, one by Dr. Fridenberg and the other by Surgeons Parsons and Segar, appeared in The Journal, April 6 and 13, respectively.

The portion of Fridenberg's article which you quote as authority, "It has been generally assumed that a normal labyrinth is sine qua non and the only essential for equilibration," is most unfortunate—unfortunate, because untrue. Through discussions with medical men and the perusal of literature generally, I am not aware that any such general assumption exists. Quite the contrary, all writers on and men familiar with the subject of equilibration distinctly emphasize the fact that it requires a harmonious cooperation of several special senses for the maintenance of normal equilibrium, namely, that of the visual sense, muscle sense and the kinetic-static or so-called vestibular sense. Thus, normal equilibration depends on a tripod, as it were; but whereas with the visual and the muscle-splanchnic sense equilibration is only a collateral function, the kinetic-static sense differs from them in that equilibration and orientation are its sole and only functions. The immediate effect from the loss of the visual sense is blindness and not loss of equilibration; similarly, a disturbance in the function of the muscle and splanchnic sense does not produce loss of equilibration per se, whereas, on the other hand, an affection of the kinetic-static mechanism, no matter how slight—a point of congestion in the labyrinth perhaps the size of the head of a pin—is immediately made manifest by gross equilibratory disturbances. These are facts that every observing physician has seen for himself. It is not assuming too much, therefore, to say that the kinetic-static or internal ear mechanism is the chief but by no means the sole organ of equilibration.

It is self evident that in order to guide an aeroplane safely one needs a perfect equilibratory equipment, that is, a perfect internal ear mechanism and a normal visual mechanism, as well as an unimpaired muscle and tactile sense. To say that the medical advisors of the U. S. Army are not aware of a proposition so obvious as this is to credit them with stupidity. All one need do is to refer to the examination blanks giving the outlines of the physical requirements for aviators in detail to see that they are perfectly aware of the fact that a blind man or one with poor visual or color sense acuity is not good material out of which aviators are made. The fact is that careful and detailed examination of the eyes as well as of other special senses is undertaken as a matter of routine, with this addition, that in view of the importance of the internal ear and its intracranial pathways in the function of equilibration, most careful tests are performed in order to determine the integrity of this mechanism. The examination of this special sense is not made at the *expense of* any other special sense; it is simply an addition with the view of assuring the prospective aviator of a most perfect physical equipment for his work.

You also quote as "further evidence" the findings of Surgeons Parsons and Segar, namely, that in *many cases* the best ratings as aviators were obtained by men who had made the worst showing under the Bárány tests. In their contribution they have divided the fliers into three classes, "good," "average" and "poor," and have shown that the average nystagmus response of the good fliers was 24.2 seconds, whereas the average response of the poor fliers was 24.8 seconds. In other words, the poor fliers had on an average 0.6 second nystagmus longer than the good fliers. Assuming this to be true, it argues nothing against the value of the turning chair in the examination of fliers for the simple reason that in their analysis there is not a single instance of a good flier with no nystagmus or poor nystagmus. The fact that some individuals with a normal nystagmus will not make good aviators is conformable to a very well known fact that many persons with nimble and perfectly jointed fingers and arms will not make excellent piano players. The reason is simple: In order to become a good piano player, one needs other qualifications in addition to nimble fingers; similarly, in order to become a good flier, one needs other qualifications in addition to a perfect equilibratory mechanism. Supposing one were to set out to train a hundred persons to become piano players or violinists, one would at least make certain when selecting the candidates that none with "stiff joints" entered the group, remembering all the time that not all perfect-jointed persons would turn out to be good musicians. The position of the Army board is very similar: In choosing candidates for its flying personnel, it wants to make certain that they are at least free from any apparent physical defects that would greatly handicap them in their work, remembering at the same time that many persons with physically perfect attributes may lack that additional something which utilizes good physical material and shapes it into the perfect product. The facts adduced, therefore, from the contribution of Parsons and Segar simply endorse the stand the Army is taking, namely, that no good fliers are likely to be produced from men who have a poor or impaired equilibratory mechanism.

You refer to the statement of Surgeon H. Graeme Anderson of the Royal Navy in which he says:

> It has been assumed that sound equilibration and muscle sense is essential to flying, so that the aviator would be conscious of his position in space, realize at once any deviations therefrom, and correct these quickly. But in fog it has been found almost impossible to detect any deviation during flight. Time and again aviators coming out of the dark clouds or fog have found themselves flying one wing down, and it has been recorded that some have flown upside down without knowing it. Thus it is obvious that most of the impressions which control balance in flying come through the eyes.

It does not seem to be quite clear what he means when he says "but in fog it has been almost impossible to detect any deviation during flight." Does he mean deviation of the aeroplane from its true level? How, then, was this balancing accomplished? Surely not through the sense of sight: the eyes are of not much service in a fog. It must be, then, by means of the ears and muscle sense that equilibrium was maintained. The statement that it has been recorded that some have flown upside down without knowing it cannot be accepted in all seriousness. A captain and a major in the Flying Corps stationed at Essington, Philadelphia—pioneers in flying with the U. S. Army—definitely stated to me that such a thing is impossible; that when looping the loop or when performing any of the other aerial evolutions it is absolutely inconceivable and in their own experience impossible for a flier not to know when he is upside down. The surgeon's conclusions, then, that "it is obvious that most of the impressions which control balance in flying come through the eyes," are by no means so obvious.

In the experiment which Surgeon Anderson had carried out himself when he was taken up in an aeroplane blindfolded, he states that he was able to describe the position in space at various times, that is, he was able to do this during the climbing and flying with the right wing and with the first spiral downward to the right. He was blindfolded all the time. How could he do it unless the internal ear mechanism came to his aid? Surely any special sense that can tell the aviator this much is a definite asset to him, and the Medical Corps of the Aviation Service is not far amiss when it attempts to make certain that such a mechanism is normal before accepting a candidate for the Flying Corps. True, Surgeon Anderson in this experiment also states that he was not able to tell all the time all possible evolutions of the plane. We do not know if his vestibular mechanism is normal, as he was not examined in the turning chair: but assuming even that he is normal, it is simply in accord with our general knowledge that the eyes do play a rôle in equilibration and orientation, and no one realizes this better than the personnel in charge of the Aviation Corps, as is evidenced by the exhaustive and thorough eye examination to which every applicant of the Flying Corps is now and always has been subjected.

Summing up, the status of the Bárány tests from the standpoint of the aviator amounts to this: The internal ear and its intracranial pathways have for their sole function equilibration and orientation; therefore, this mechanism is a most important unit in the entire "equilibrium complex" of an individual. Since perfect equilibratory function is so important to the aviator, common prudence would suggest that each one of the mechanisms concerned in this function be carefully examined. The internal ear mechanism receives particular attention since it is peculiarly adapted for sensing motion and secondarily, position. It is examined in the turning chair, in which different portions of the mechanism are tested. We start with the assumption that a normal mechanism will produce normal responses. These normal responses are (1) nystagmus of a certain type and duration, and (2) vertigo of a certain duration which is made manifest to the examiner objectively by past-pointing and falling. When turning in the chair fails to produce normal nystagmus, vertigo, past-pointing and falling, it is assumed that there must be a definite reason for it. It is not considered that "it just happened so," but is looked on as due to an impairment of the inner ear or of its intracranial pathways. Such a person would therefore start with a handicap and is disqualified.

The otologists of this country have rendered our government a distinct service by pointing out the importance of the vestibular apparatus in aviation. The ability to simplify and standardize the tests, so that large numbers of applicants can be easily examined, added largely to the feasibility of such an examination and should redound to their credit. It is to be regretted, therefore, that doubt and mistrust should be sown throughout the profession at large solely because of a lack of a thorough understanding of the subject.

Lewis Fisher, M.D., Philadelphia.

◆

To the Editor:—In his article on "Visual Factors in Equilibration, Especially Aviation" (The Journal, April 6, 1918, p. 991), it is apparent that Dr. Fridenberg has been under a misapprehension as to the character and scope of the physical examination of applicants for flying service. Let me first recommend that he secure Blank 609, A. G. O., which is the physical examination blank for these applicants. He will at once be struck by the fact that of the thirty-two items of this examination, the first twelve are solely concerned with a complete examination of the eye. On the other hand, he will be equally struck with the fact that only one item (No. 20) deals in any way with the internal ear balance mechanism. This, I think, will give him a different attitude toward the ideas of those concerned in the examination of applicants for this service, and will go far to reshape the impulse which prompted him to say, "It has generally been assumed that a normal labyrinth is the sine qua non and the only essential for equilibration."

It will also assure him that as far as concerns his views expressed immediately following this quotation, they are entirely in accord with the views of the Chief Surgeon of the Aviation Section, namely, "this would be a very one-sided point of view, and that there exist other important factors of equilibrium which should not be overlooked." His statement that the "visual factors particularly have been overlooked" is only indicative of his having been misinformed as to the scope of the examination. The same comment applies to the sentence immediately following, in which he warns against neglecting "other factors in balance and vertigo," etc.

In stating that the "labyrinthine tests refer, naturally, to rotational vertigo alone," and then proceeding to call attention to the fallacy of the "view that all vertigo is rotational and therefore labyrinthine," he evidences a most unfortunate misapprehension of the otologic concept underlying the vestibular test. This is so simple that its soundness seems difficult to question. It is conceived that the individual selected to undergo special training as an aviator should be determined to possess normal physical equipment; his bones and muscles, cardiovascular, respiratory and gastro-intestinal apparatus should be normal; his intracranial and special sense equipment should be normal. One of the special senses to be subjected to scrutiny in this examination is the vestibular sense, the sole special function of which is perception of motion. We are in possession of information concerning the normal responses to tests of this special sense, and exactly so far as we are able to conduct such tests should we see to it that this special sense of motion perception should show as nearly a normal acuity as the special sense of light perception, which is required to show $^{20}/_{20}$ visual acuity.

One of the means of ascertaining that normal acuity of vestibular perception is present is the rotating chair. In subjecting this motion-perceiving special sense to its normal stimulus, namely, motion, it was determined to be most practical to apply this stimulus by means of a rotating chair, as the application of motion in a linear direction, for the period of time and in the intensity necessary to elicit certain responses to a standard stimulus, would necessitate apparatus entirely too bulky to be susceptible of practical application under ordinary conditions of office examination. By making use of a rotational motion stimulus instead of a linear motion stimulus, it was possible to work out a standard means of applying a motion stimulus in certain definite quality and quantity in a manner, and by means of an apparatus, easily handled in an office. For this reason, the subject of the tests of the vestibular apparatus is made to experience rotational vertigo. The definition of this vertigo is "the sensing of motion not in accord with fact." In other words, stimulation of the end-organ of this apparatus is set up, and lasts for a certain standard length of time in the normal; during the continuation of the stimulus, if the sensing apparatus is intact, the subjective appreciation of the stimulus continues; since the subjective appreciation in the normal is both quantitative and qualitative, and since the form of stimulus has been rotation, the consequent subjective perception is a rotational motion, or is rotational vertigo.

Dr. Yandell Henderson, professor of physiology at Yale University, described to me a similar test of his vestibular apparatus which he underwent unexpectedly during an inspection trip in a deep mine in Yorkshire, England, in company with Professor Haldane and some others. They were subjected to a very rapid ascent, in an elevator, vertically upward for a considerable period of time, after which he experienced a disquietingly convincing sensation of falling vertically downward; whereas in reality his vertically upward trip was continuing, but at a markedly slower rate of speed, as he learned afterward to his relief. This is exactly the kind of test to which a man is subjected in the rotating chairs, except that the character of motion stimulating the vestibular end-organs was in this instance linear motion rather than rotational motion. Just as following the rotation to the right, during the period of the consequent stimulus of the vestibular apparatus, the subject experiences the sensation of motion of the same character, namely, rotational, but in the reverse direction, or to the left, so Dr. Henderson experienced, after an intense stimulus of linear motion in a vertical direction upward, the natural reactionary sensation of linear motion rather than rotational, and in the opposite direction, or downward. I hope I have made it clear that the only object of testing a man in a rotating chair is to determine the degree of accuracy of his perception of motion, both qualitative and quantitative, and that the matter of inducing rotational vertigo is purely incidental to the use of the rotating chair, as it constitutes the most practical and convenient form of motion-producing apparatus for tests of this kind.

In referring to labyrinthine diseases, Dr. Fridenberg gives evidence of having failed to take into account that type of disease which is far more common and of more practical importance in connection with the subject in hand than the suppurative or infectious type of labyrinthitis, namely, the toxic type. I need only to refer, in this connection, to a few of the case reports which we have of applicants determined to possess normal vestibular acuity of motion perception at the time of their admission into the service, and who later on developed mumps, with secondary specific eighth nerve involvement, after the subsidence of which they showed a marked impairment of their acuity of motion perception.

I do not understand exactly how Dr. Fridenberg feels so certain that the possessors of dead labyrinths are not apt to try to fly, unless it be on the *a priori* grounds that the function abrogated in them is of considerable importance in flying. If I am correct in conceiving that he senses this importance of this function, it only goes to show that we, after all, are in accord in regard to the matter of appreciating the importance of the vestibular function to the aviator. I feel, indeed, that we are, because of what he proceeds to say, "In the first place, such defective labyrinths would have been detected in the course of instruction over the aviation field, or, at least, during the first trial flights." This statement could not have been made by a man who was not thoroughly in accord with the belief that the labyrinthine function is of great importance to the flier.

It is gratifying to note that his ideas concerning the possibility of explaining falls in flying machines coincide with those of the Chief Surgeon's Staff, as proved by his mention of other factors, such as the "effects of altitude and temperature on normal but susceptible organisms . . . and including, besides, cardiac syncope, embarrassed respiration or circulation, and panic fear." So much importance is laid on the possibility of these factors impairing the efficiency of the aviator in flying, that special cardiovascular, psychologic and physiologic departments have been established in the Medical Research Laboratory for the study of conditions which may constitute underlying factors in the development of these forms of danger to the flier.

In further mentioning the details of conditions which may give rise to vertigo and consequent loss of control solely attributable to visual perception—"viewing objects in rapid or irregular motion, such as storm driven clouds, waves, masses of water tumbling over a fall or pouring through a flume . . . irregular illumination and motion of objects alone . . . the common or field variety of 'movie' headache and dizziness . . . a swinging mirror," he again evidences being in complete accord with the views of the chief surgeon and his staff in perceiving the possibility of the aviator suffering disaster attributable to misinformation from visual illusions or unusual stimulations. In this connection, he has laid himself open to the charge of being inconsistent, however, since his article intones the importance and reliability of visual information concerning orientation of oneself in the air without sounding a note of warning against the ever present possibility of being brought to disaster by visual illusion or misinformation, and in the same article he states that "normal labyrinths merely supply the possibility of vertigo and false sensations of direction and space." It is equally true of all the special senses that sensory illusion and misinformation are always possibilities, and cognizance of the conditions apt to result in such illusions and misinformations should be very carefully taken in the effort to safeguard the aviator as fully as possible. It is manifestly as absurd to say "normal labyrinths merely supply the possibility of vertigo [which is only the sensing of motion not in accord with fact] and false sensations of direction and space," and that "one might even venture the paradox that the safest aviators would be those with dead labyrinths," as it would be to call attention to what he has just mentioned previous to this statement of the possibility of normal eyes being the medium of bringing to their possessor illusions or misinformation only, and to proceed with the observation that therefore the safest aviators would be those lacking eyes. It is unnecessary for him to assure me that this is not his thought, and I beg him to forgive me for even alluding to it; but I felt that it was worthy of mention in passing, since he had opened the subject, as quoted.

He asks the question, "Just how much of a handicap is a dead labyrinth for accurate and delicate balancing?"

I am fortunately in position to answer that question in this way: A series of examinations of the functional activities of the labyrinths of whirling dancers, head balancers, equilibrists, tight and slack wire performers, and various other circus and vaudeville stunt performers has been made by numerous observers, and findings in these examinations are on record in the Medical Research Laboratory. In each case, these artists were found to be possessed of full normal vestibular acuity. It seems unnecessary to attempt to adduce arguments in favor of the desirability of the aviator, the whirling dancer, the equilibrist, and the like, possessing at least approximately normal sense organ equipment of the four special senses cooperating to furnish man with information concerning motion. It is difficult to decide which, if any, could be dispensed with without leaving him less adequately equipped to indulge in such delicate and accurate motor coordinations as are necessary to the successful execution of flying, balancing stunts and whirling dances.

I feel very strongly that Dr. Fridenberg's statement that "the body position is brought into correspondence with a *visually* sensed standard, in this case a vertical line," and that "if the standard chosen is false, if the line is not exactly vertical, error will be manifested," is not entirely correct. It is my profound conviction, and I find that it is also the conviction of others with whom I have discussed this point, that the correlation of all incoming information in the sensory and psychic sensoria of normal man would result in the discovery that the vertical visual sense standard was false, through the intermediation of deep sensibility sensing the direction of the pull of gravity, which would result in the normal individual being made aware of the falsity of the visually selected vertical standard by reason of its failure to be in accord with the deep sensibility information as to the direction of the pull of gravity, which is always vertically downward; and that subconscious correction would be made and error thus not be manifested, but avoided.

Among the subjects occupying the special attention of the Medical Research Board, in connection with the study of the physical welfare of the flier, is the special sense of deep sensibility, and the associated voluntary and involuntary motor coordinations and control of the body in accord with afferent impulses from this tract. Recognition was accorded long ago to the fact that this sense plays an important part in the execution of body movements and controls incidental to maintaining balance. In observing that "these factors . . . have been almost entirely neglected in favor of a one sided and exclusive attribution to the labyrinth of balance control functions," it is again apparent that we are in accord concerning our conception of the importance of things in general, and that Dr. Fridenberg is again the victim of unfortunate misinformation as to the scope of the work of the medical examiner of the Aviation Service (compare Tests 19 and 21, Blank 609, A. G. O.).

Particularly apropos is his quotation of the letter from an American aviator in France, describing his own sensations in flight when unable to see, and dependent on his labyrinthine balance sense:

> While in the air at about 700 meters, some low hanging clouds blew down, enveloping me completely, and likewise losing me completely. For a half hour I wandered around vainly trying to get my bearings. . . . When you get into very thick clouds, it is impossible to tell whether you are in *ligne de vol*, that is, flying level, for there is no horizon visible to gage by. Frequently, an aviator will come out into clear space and find himself on the verge of a wing slip.

I cannot conceive any more convincing proof of the practical value of the service of the labyrinth and deep sensibility tracts than that contained in this quotation. This man was certainly deprived of any useful information coming along his visual tract during the time that he was utterly unable to see anything on account of the cloud. Yet, for half an hour he was able to wander around without meeting disaster, during which period he was thrown solely on the guidance of his balance senses. He certainly could not see, taste, smell or hear, or by touch feel where he was or in what position with relation to the pull of gravity he was, yet for half an hour some special sense succeeded in guiding him so safely that he avoided disaster. This seems to be eloquent testimony as to the practical value of normal balance senses.

Once more I find that Dr. Fridenberg and I are in accord concerning ideas as to visual requirements in his last paragraph. The question of hypersensitiveness to bright light, sharpness of the sense of motion, especially at the periphery of the retina, photometric variations within normal limits, and a variety of other special examinations of the visual function are in process of study, and standards for the aviation service are being developed at the Medical Research Laboratory.

EUGENE R. LEWIS, M.D., Mineola, L. I., N. Y.
Major, M. R. C., U. S. Army.

UNFAVORABLE SALVARSAN REPORTS—VERBOTEN

To the Editor:—I subtend a copy of a letter received day before yesterday. The letter is written on the stationery of O'Gorman, Battle & Vandiver, Attorneys and Counselors at Law, 37 Wall St., New York City:

May 22, 1918.

James C. Sargent, M.D.
Room 838, Wells Bldg.,
Milwaukee, Wis.

Sir:—We represent Mr. Herman A. Metz, President of the Farbwerke-Hoechst Co., distributors, under Federal License, of Salvarsan,

Mr. Metz directs us to call your attention to an article published over your signature in THE JOURNAL of the American Medical Association in its issue of March 30, 1918.

Mr. Metz directs us to inform you that the publication of this article and the statements therein were seriously damaging to the Farbwerke-Hoechst Co., and directs us to say further to you that he and the Corporation will hold you personally responsible for any repetition, oral or written, of the same or similar statements to the same effect.

He directs us to say further to you that the lot of Salvarsan received by you from the Farbwerke-Hoechst Company was tested before being sent you by Prof. Gies, by the United States Public Health Service and clinically in a New York hospital, and after the publication of your article ampules from the same lot were re-tested by the same parties and reported satisfactory, and that practically every physician who received some from the same lot made no adverse reports thereon.

Very truly yours,
(Signed) O'GORMAN, BATTLE & VANDIVER.

This I take to be a rather peculiar attempt at the solution of a scientific problem.

JAMES C. SARGENT, M.D., Milwaukee, Wis.

[EDITORIAL COMMENT:—A brief scientific article appeared in THE JOURNAL of March 30, 1918, by Dr. J. C. Sargent entitled "Toxicity of the American-made Arsphenamin (Salvarsan)." The article recorded untoward results following the injection of some Salvarsan made in New York by the former representative of the Farbwerke-Hoechst Co. of Germany. Dr. Sargent now receives the letter reproduced above. This attempt on the part of the Farbwerke-Hoechst Co. to control a scientific discussion of pharmacologic facts by intimidating physicians who would report facts that happen to be unfavorable to the product in which that concern has a proprietary interest will, doubtless, be appraised by American physicians at its face value. Possibly the Farbwerke-Hoechst Co. hold the Teutonic opinion that "Yankees" are "idiotic." They will find, however, that American physicians cannot be bulldozed into silence regarding the untoward effects of a proprietary remedy, even if that remedy did originate in Germany.]

Alcohol and Work.—Alcohol gives a sham sensation of added force and in reality decreases the ability to do work. Alcohol is the greatest cause of misery in the world, and as Cushny has put it, if alcohol had been a new synthetic drug introduced from Germany, its importation would long since have been forbidden. On the other hand, good beer makes poor food taste well. It also frequently leads to overeating. The cure for bad food is to have our daughters taught how to cook a decent meal. After that we can talk about prohibition. —Lusk, Food in War Time.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALABAMA: Montgomery, July 9. Chairman, Dr. S. W. Welch, State Capital, Montgomery.

ARIZONA: Phoenix, July 2. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

CALIFORNIA: San Francisco, June 25. Sec., Dr. C. B. Pinkham, State Capitol, Sacramento.

COLORADO: Denver, July 2. Sec., Dr. D. A. Strickler, 612 Empire Bldg., Denver.

CONNECTICUT: New Haven, July 9-10. Sec. Regular Bd., Dr. Chas. A. Tuttle, 196 York St., New Haven; Sec. Eclectic Bd., Dr. J. E. Hair, 728 State St., Bridgeport; Sec. Homeo. Bd., Dr. E. C. M. Hall, 82 Grand Ave., New Haven.

DELAWARE: Wilmington, June 18-20. Sec., Dr. H. W. Briggs, Wilmington, Del.

DISTRICT OF COLUMBIA: Washington, July 9-11. Sec., Dr. E. P. Copeland, The Rockingham, Washington.

FLORIDA: (E): Jacksonville, June 10-11. Sec., Dr. G. A. Munch, Tampa.

FLORIDA (Regular): Jacksonville, June 17-18. Sec., Dr. W. M. Rowlett, 812 Citizens Bk. Bldg., Tampa.

GEORGIA: Atlanta and Augusta, June 4, 5. Sec., Dr. C. T. Nolan, Marietta.

ILLINOIS: Chicago, June 3-7. Mr. F. C. Dodds, Supt. of Registration, Capitol Bldg., Springfield.

INDIANA: Indianapolis, June 13-15. Sec., Dr. W. T. Gott, 84 State House, Indianapolis.

IOWA: Iowa City, June 6-8. Sec., Dr. G. H. Sumner, Capitol Bldg., Des Moines.

KANSAS: Topeka, June 18-19. Sec., Dr. H. A. Dykes, Lebanon.

LOUISIANA: New Orleans, June 6-8. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

MAINE: Augusta, July 2-3. Sec., Dr. Frank N. Searle, 776 Congress St., Portland.

MARYLAND: Baltimore, June 18-22. Sec., Dr. J. McP. Scott, Hagerstown.

MICHIGAN: Ann Arbor, June 11-13. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

MINNESOTA: Minneapolis, June 4-6. Sec., Dr. T. S. McDavitt, 741 Lowry Bldg., St. Paul.

MISSOURI: St. Louis, June 17-19. Sec., Dr. George H. Jones, State House, Jefferson City.

NEBRASKA: Lincoln, June 3-5. Sec., Dr. J. J. Hompes, 612 Sec. Mut. Bldg., Lincoln.

NEW HAMPSHIRE: Concord, June 24-25. Sec., Dr. W. T. Crosby, Manchester.

NEW JERSEY: Trenton, June 18-19. Sec., Dr. Alex. MacAlister, Trenton.

NORTH CAROLINA: Raleigh, June 24-28. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.

NORTH DAKOTA: Grand Forks, July 2. Sec., Dr. G. M. Williamson, Grand Forks.

OHIO: Columbus, June 4-7. Sec., Dr. H. M. Platter, State House, Columbus.

OKLAHOMA: Oklahoma City, July 9-10. Sec., Dr. J. J. Williams, Weatherford, Okla.

OREGON: Portland, July 2. Sec., Dr. Herbert S. Nichols, 802 Corbett Bldg., Portland.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 9-13. Sec., Dr. N. C. Schaeffer, State Capital, Harrisburg.

RHODE ISLAND: Providence, July 11. Sec., Dr. B. U. Richards, State House, Providence.

SOUTH CAROLINA: Columbia, June 11. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

SOUTH DAKOTA: Deadwood, July 9. Sec., Dr. P. B. Jenkins, Waubay.

TENNESSEE: Knoxville, Memphis and Nashville, June 14-15. Sec., Dr. A. B. DeLoach, Exchange Bldg., Memphis.

TEXAS: Austin, June 18-20. Sec., Dr. M. F. Bettencourt, Mart.

UTAH: Salt Lake City, July 1-2. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City

VERMONT: Burlington, June 10-12. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 18-21. Sec., Dr. J. W. Preston, Roanoke.

WASHINGTON: Tacoma, July 2. Sec., Dr. C. N. Suttner, 415 Old Nat'l Bldg., Spokane.

WEST VIRGINIA: Wheeling, July 9. Health Com., Dr. S. L. Jepson, Masonic Bldg., Charleston.

WISCONSIN: Milwaukee, June 25-27. Sec., Dr. J. M. Dodd, Ashland.

Wyoming February Examination

Dr. H. E. McCollum, secretary of the Wyoming State Board of Medical Examiners, reports the written examination held at Laramie, Feb. 6-8, 1918. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 5 candidates examined, 4 passed and 1 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Bennett Medical College	(1911)	75.9
University of Nebraska	(1904)	88.5
Ohio State University College of Medicine	(1917)	85.9
Vanderbilt University	(1887)	83.9
FAILED		
Starling Medical College	(1881)	*

* No grade given.

Massachusetts Service Examinations

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the special oral, practical and written examinations held for recent graduates eligible for war service, at Boston, Feb. 12-13, and March 12-13, 1918. The examinations covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Sixty-eight candidates were examined, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1917)	82.5
Harvard University	(1918)	75.4, 76.3, 76.8, 77, 77.1, 77.6, 78.5, 78.9, 79, 79.3, 79.5, 79.5, 79.5, 79.6, 79.6, 79.7, 80.2, 80.5, 80.7, 80.7, 80.9, 81, 81.5, 81.5, 81.6, 81.7 81.9 81.9, 82.2, 82.5, 82.6, 82.9, 83.5, 83.7, 84, 84.2, 85.2, 89.5.
Tufts College Medical School	(1918)	75, 75, 75.1, 75.7, 76.5, 76.6, 76.7, 77.3, 77.8, 78.4, 78.8, 78.8, 79, 79.1, 79.5, 79.6, 79.7, 80.3, 80.6, 80.7, 80.7, 81.1, 81.1, 81.5, 81.7, 81.9, 82, 82.7, 84.

Massachusetts March and Special Examinations

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, practical and written examination held at Boston, March 12-14, 1918. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 63 candidates examined, 49, including 6 osteopaths, passed, and 14, including 6 osteopaths, failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Columbian University	(1893)	82
Rush Medical College	(1900) 84.6; (1904)	75
Bowdoin Medical School	(1907)	75
Maryland Medical College	(1908) 75; (1911)	82
Boston University	(1916)	75
College of Physicians and Surgeons, Boston	(1910)	75.7
Harvard University	(1917) 82, 84.1; (1918)	79.7, 80.2, 81.5, 82.4, 83.4, 83.7, 83.8, 85.2, 85.3, 86.7, 87.
Tufts College Medical School	(1917) 77.1, 77.5; (1918)	75, 75, 75.2, 77.3, 77.3, 78.2, 78.5, 78.7, 79, 79.5, 79.9, 80.2, 80.3, 81.2, 82.9, 83.1.
Detroit College of Medicine	(1895)	77.2
Washington University	(1908)	81.1
Columbia College in the City of New York	(1893)	82.8
Cornell University	(1915)	85.8
FAILED		
College of Physicians and Surgeons, Baltimore	(1902)	66.2
College of Phys. and Surg., Boston	(1915) 65; (1916)	69.5, 70.6
Tufts College Medical School	(1918)	67, 72.9
Meharry Medical College	(1915)	72.3
University of West Tennessee	(1916)	63.7

Dr. Bowers also reports that special examinations for war service were held at Boston, Jan. 17 and Jan. 29, 1918, at which three candidates were licensed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Harvard University	(1916) 82.2; (1917)	82.5
University of Oklahoma	(1917)	80

Minnesota April Examination

Dr. Thomas S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the written, oral and practical examination held at Minneapolis, April 2-4, 1918. The examination covered 15 subjects and included 80 written questions. An average of 75 per cent. was required to pass. Sixteen candidates were examined, all of whom passed. Five candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Rush Medical College	(1916) 86; (1918)	91
Harvard University	(1918)	91
University of Minnesota	(1917) 84; (1918)	84, 85, 87, 88, 88, 89, 89, 89, 90, 92, 94.
John A. Creighton Medical College	(1917)	90

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
Chicago Homeopathic Medical College	(1900)	N. Dakota
College of Physicians and Surgeons, Chicago	(1905)	Arkansas
Kentucky School of Medicine of Louisville	(1898)	Indiana
Southern Homeopathic Medical College	(1902)	Maryland
Washington University	(1916)	Missouri

Rhode Island April Examination

Dr. Byron U. Richards, secretary of the Rhode Island State Board of Health, reports the practical and written examination held at Providence, April 4-5, 1918. The examination covered 7 subjects and included 70 questions. An average of 80 per cent. was required to pass. Of the 6 candidates examined, 4 passed and 2 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Harvard University	(1918)	84.7, 87.5, 88
Tufts College Medical School	(1918)	86.1
FAILED		
Maryland Medical College	(1913)	77.2
Tufts College Medical School	(1918)	77.8

Social Medicine, Medical Economics and Miscellany

THE EVOLUTION OF THE BULLETIN OF THE CHICAGO HEALTH DEPARTMENT

W. A. EVANS, M.D.

Chicago

In 1903, a well known secretary of a state board of health, in conversation, spoke disparagingly of the bulletin of the Chicago Health Department. He thought it undignified. He did not approve of its bid for public attention. His own report was of the orthodox type—pages of tables of statistics.

The Chicago bulletin of the last ten years makes the bulletin of 1903 look very conservative, yet practically every health department is now issuing bulletins of the same general type as that issued by Chicago.

Chicago's gross death rate fell below 15 per thousand in 1900 and has remained below that line since. For cities situated geographically as Chicago and with approximately Chicago's distribution of population, a death rate persistently somewhat below 15 per thousand may be considered as on a normal level. It is not without significance that Chicago reached this level several years in advance of other cities with which it may properly be compared.

To my mind, a considerable part of this achievement is due to the fact that Chicago very early saw the advantage of going to the people through its health department bulletin and other publications. It will be of interest, therefore, to study the evolution of the bulletin.

In 1870, Dr. John H. Rauch gathered up the loose material relative to early health work in Chicago, publishing it in "Chicago's Sanitary History from 1833 to 1869." Since 1870, the health department has published an annual report, but it has frequently happened that several annual reports were combined in a single volume. These annual reports were statistical in character and were evidently intended solely for health departments and libraries. In 1911, a report comprising annual reports for 1907, 1908, 1909 and 1910 was issued. This report differed from the others in that it contained much of material for public education in addition to the charts, diagrams and tables found in preceding reports.

The annual reports, however, are of far less interest than the bulletin. The evolution of the latter publication is interesting from several standpoints. Outside of the annual report, the first periodical publication of the Chicago Health Department, the ancestor of the present bulletin, that I have been able to find was dated July, 1890. It is a four-page quarto publication. Its title was "Health Department, Condensed Statement of Mortality." Two pages were given to vital statistics, one to meteorological summary and one to the title. I have not been able to find any copies of numbers issued between July, 1890, and January, 1894.

The issue of January, 1894, was also a four-page quarto, the title being the same as that of July, 1890. The arrangement differed in that the lower half of the first page was given over to vital statistics, the lower half of the third page to a meteorological summary, and the fourth page to educational propaganda. The propaganda articles dealt with smallpox, water, milk and a few other subjects. There was a ward map of the city on this page. Page 2 and the upper part of page 3 were devoted to statistics. This arrangement of the bulletin continued through the year, except that the contents of the fourth page gradually became statistical in character.

January, 1895, the title was changed to read, "Department of Health, City of Chicago, Bureau and Division Reports." During that year the bulletin was a two-page statistical report carrying nothing except vital statistics. The January and February, 1895, numbers had three pages of statistics showing the work of the different bureaus. One and a half pages were devoted to statistics of deaths, and the meteorological data reappeared.

In the March, 1896, number the educational page reappeared. In this number also we find charts, one of which showed the sanitary quality of the water supply by months, the other, the typhoid and diarrhea mortality rates.

In the May number, the fourth page was entitled, "Notes and Comments by the Assistant Commissioner." Dr. F. W. Reilly was the assistant commissioner. In August an effort was made to solve the midwifery problem. The fourth page of the bulletin gave the names and addresses of obstetricians willing to answer calls for assistance from midwives. In 1897, the same arrangement was followed. The June number contained an editorial on the "First Year's Work on Medical Inspection of Chicago Schools." By autumn, the bulletin had become a booster for "the healthiest large city in the world."

In 1898 the same plan was followed. The leading educational article in the July number was on "Development of Sanitary Science—the Daily Press as a Potent Auxiliary." In the fall of 1898, there was an epidemic of meningitis in Chicago. The October bulletin, in addition to the usual four pages of matter, had an additional four pages on meningitis.

In 1899, the arrangement continued the same, except that the space given to educational matter other than statistics was increasing, month by month. In June, 1899, the title was changed to read, "Department of Health, City of Chicago, Monthly Bulletin." The educational portion now occupied six pages and came first in the publication. This was followed by four pages of statistics. The August, 1899, number devoted four pages to an analysis of the water situation and demonstrated that the drainage canal was not lowering the level of the lake. After August, for the the remainder of 1899, there did not appear to be any more educational matter carried in the bulletin. The publication consisted of only four pages of statistics and was entitled, "Bureau and Division Reports." The first numbered bulletin was that of December, 1899. It was numbered Vol. VI. No. 12.

The issues from January to September, 1900, inclusive, entitled, "Department of Health, City of Chicago, Bureau and Division Reports," consisted of four pages of statistical matter. The October number again consisted of two portions. The first, termed "Monthly Bulletin," was devoted to the housing problem, and was written by Dr. A. R. Reynolds, health commissioner. The December number also had a section entitled "Monthly Bulletin." It contained a study of self-purification of streams by Dr. Reynolds.

From January to July, 1901, the bulletin was issued in two parts, "the Monthly Bulletin," educational in purpose, and a separate "Bureau Reports," statistical in character. In the latter half of that year, the title "Monthly Bulletin" was retained, but the bulletins generally consisted of four quarto pages containing statistics, mostly vital statistics, and a few editorial comments. Chicago's rather famous vaccination creed appeared for the first time in this year.

The bulletin seems to have been wholly discontinued in 1902. July 5, 1902, a weekly statement under the title "State of Chicago's Health" was begun. It appeared in every Chicago English daily paper. It varied from a half column to two columns and carried mortality statistics, a short list of the causes of death, and some educational matter. Nov. 8, 1902, the title was changed to "State of Chicago's Health, Bulletin of the Health Department," No. 45.

This plan of a weekly article in the daily papers was continued throughout 1903 and 1904. The plan was to write the article at the end of the statistical week—Saturday noon—and send it at once to the Chicago *Record-Herald*. This paper set it up and furnished galley proofs to the other papers and to the department. The department kept a file of its galley proofs. The data consisted of vital statistics and educational propaganda material. The matter was set in newspaper editorial type, and was arranged on a double column galley with the words "State of Chicago's Health" extending in large letters across the two columns.

Jan. 13, 1906, the bulletin became a four-page octavo pamphlet. The first page was given over to the title, "City of Chicago Bulletin of the Department of Health, Charles J. Whalen, Commissioner, 1906." The second page was headed, "State of Chicago's Health, Bulletin of the Health Department, week ended January 13, 1906, Vol. IX, No. 2." It contained two pages of educational propaganda material and a statement of mortality figures for the week, arranged on the short cause list. Most of these weekly bulletins consisted of two pages of printed matter, though by the spring of 1907, some of them had shrunk to one brief page. The plan followed in the department was to send the matter over to the *Record-Herald,* which set it up, furnished galley proofs to the other papers, and supplied the department with the matrix from which it printed its edition. The department paid messenger fees, cost of metal and a few incidentals.

Aug. 3, 1907, the bulletin underwent a most radical change. The title page of that number read:

> Physicians and others interested in the Bulletin may have it sent free of charge to their respective addresses on receipt of request to that effect. Bulletin Chicago School of Sanitary Instruction, devoted to the dissemination of advice and information of the Department of Health, City of Chicago, W. A. Evans, Commissioner, Vol. I, New Series No. 1; Vol. X, Old Series, No. 31, August 3, 1907. Published every Saturday by the School of Sanitary Instruction. Application made at Chicago, Illinois, for entry as second-class matter.

Vol. I, No. 5, Aug. 31, 1907, changed the last item to read, "Entered at Chicago, Ill., as second class matter."

The money saved on postage was used to send out an increased number of copies of the bulletin. In 1907, the department of health was incorporated with the secretary of state as an educational institution. Since that time, the educational feature of its work has always been kept to the fore. As a rule, the issues of the publication in 1907 consisted of six pages. All the space was given to educational matter except that used for contagion, morbidity tables and the mortality statistics of the week arranged on the form of short list of causes of death, prepared by the United States Bureau of Vital Statistics.

Aug. 31, 1907, the title page first bore the following:

> "Sanitary instruction is even more important than sanitary legislation," said the late Earl of Derby, himself eminent both as sanitary instructor and as sanitary legislator. This bulletin is intended for instruction in sanitary matters chiefly among the laity. Incidentally, it should help the profession by such popular education of its clientele in nontechnical phrase.

This was abbreviated, June 5, 1915, to read, "Sanitary Instruction is even more important than Sanitary Legislation."

March 7, 1908, the system of numbering was changed so that it read, "Vol. XI, Old Series No. 530," instead of "Vol. XI, Old Series No. 10," as it would have read, had the change not been made.

In the latter part of 1909, the bulletin began to be newsier and more gossipy. About this time the healthgrams for which it attained some reputation began to appear.

Sept. 30, 1911, the years old subtitle on the second page, "State of Chicago's Health" disappeared from the bulletin. In October, 1911, the title page was again somewhat changed. The offer of the bulletin free was dropped, as was the explanation of the purposes of the bulletin. It reads, "The Bulletin is issued every Saturday by the School of Sanitary Instruction. Entered as second class matter under act of July 16, 1894." The title occupied the upper third of the first page, and the reading matter the remainder.

Such are the steps in the evolution of the bulletin of the Chicago Health Department. This publication, which the press has supported and used for stories, has been a very important factor in elevating standards of health. Scoffed at a few years ago, it has served as a pattern for health department publications throughout the country. For this reason, its evolution is entitled to a place in medical history.

Book Notices

Lecithin and Allied Substances. The Lipins. By Hugh Maclean, M.D., D.Sc., Lecturer on Chemical Pathology, St. Thomas' Hospital, London. Boards. Price, $2.25 net. Pp. 206. New York: Longmans, Green & Co., 1918.

This is another member of the valuable series of Monographs on Biochemistry, which have constituted such an important contribution to the literature of biologic chemistry and the related sciences. That the war has not prevented its publication is a credit to the publishers, and indicates that our allies are not permitting the light of science to die out during the conflict. In this series the properties of fats in general have been covered by Leathes, the present volume developing the subject of its title, which Leathes had considered only briefly. The fact that apparently every living cell contains lecithin and other fatlike substances of this class is sufficient evidence that they are of vital importance in vital processes, and hence of prime interest to all interested in biologic process, whether as physicians or biologists. These substances are referred to in medical literature with growing frequency, and yet Maclean finds it necessary to state that little or nothing is known with certainty of their physiologic function. This indicates that time has failed to corroborate the innumerable hypotheses that have been advanced as to their rôle in biology, pharmacology and immunology.

This book emphasizes to the reviewer the hope that when the war is over, and time is available for the contemplation of more essential matters, some international council may be formed to secure a uniform nomenclature for that group of substances variously designated as fats, lipoids, lipins, etc. Even if our knowledge does not permit of perfection in selecting the proper names for each substance, let us at least agree on the labels we give them, and all use the same label for the same substance. Maclean's book adds further confusion to the nomenclature by arbitrarily applying the term "lipin" to certain substances in this group, although this term has been used by preceding writers in a totally different sense. No matter if the prevailing usage is open to criticism, the entirely arbitrary application of the same term to a more restricted class can lead to nothing but confusion, and is to be deplored, especially since this book, like the rest of the series, will be universally used as the best available source for up-to-date information concerning the subject it covers.

Physicians will be particularly interested in the discussion of the function of the lecithin group, toward which the author takes an extremely conservative view, even denying the generally accepted hypothesis that lecithin plays a part in the Wassermann reaction. As to their alleged chief functions, he says:

> In practically every case it will be seen that the evidence adduced is capable of explanation in other ways than the one usually adopted, and on the whole it is not too much to say that the biological significance of the lipins is so far a closed book. There is hardly a statement made on this problem by one investigator, which is not contradicted by some other observer, and the whole subject, in so far as experimental difficulties permit, requires thorough reinvestigation. From the physical point of view the colloidal nature of the lipins is of importance in regulating certain processes in the cell; the presence of unsaturated fatty acids in the molecule is also suggestive, since the chemical reactivity of the molecule is thereby increased.

The Examination of Milk for Public Health Purposes. By Joseph Race, F.I.C., City Bacteriologist and Food Examiner, Ottawa. Cloth. Price, $1.75 net. Pp. 224. New York: John Wiley & Sons, 1918.

This volume is intended for those in charge of the examination of milk for the protection of the public health. It is not, however, a mere laboratory manual. In fact, some of the methods are given in a way that would be intelligible only to an experienced worker. There are excellent critical discussions of a variety of tests serviceable at times in a public health laboratory, as well as the various chemical and bacterial tests employed in routine work. The discussions of analytic methods are preceded by chapters dealing with the composition of milk. The book is noteworthy for its concise presentation of the problems arising in milk examination.

Medicolegal

Liability for Gangrene

(Perry v. Rancourt et al. (Me.), 102 Atl. R. 233)

The Supreme Judicial Court of Maine overrules a motion by defendant Rancourt for a new trial after the plaintiff recovered a verdict against him of $8,192.40 for alleged malpractice in the treatment of a fracture of what was described as the lower left leg, caused by a fall on a sidewalk. The court says the plaintiff alleged that the defendants did not use proper care and skill in reducing the fracture, but bandaged his leg and put on a plaster cast so tightly as to impair the circulation of blood in his leg and foot, and allowed the cast to remain on so long that the foot and leg became gangrenous and in so diseased a condition that, on account of the defendants' negligence, his leg had to be amputated at a point nearly up to the body. That the plaintiff's leg had to be amputated on account of the development of gangrene from some cause was conceded by everybody. The plaintiff contended that the evidence was sufficient to show that the gangrene resulted from the negligence and unskilful treatment of the defendants. The defendants combated that contention, not only on the ground that the treatment was proper but also on the theory that the bacillus, called a gas bacillus, which produced the gangrene in this case could not have been generated by continued pressure of the cast.

The contention of the defendants that they were not negligent as to the pressure of the cast and the length of time they kept it on the leg was purely a question of fact for the jury, and without quoting the evidence on this branch of the case at all, the court is of the opinion that the finding of the jury on this question cannot be disturbed. But the defendants said that, even if the cast was kept on the leg as claimed, it did not produce the gangrene which necessitated the amputation of the leg. They based this contention purely on the theory that the type of gangrene here found could not be produced by pressure. From the testimony of all the physicians, however, it was fully established that continued pressure sufficient to stop the circulation might produce gangrene. There was, moreover, before the jury a definite assignable cause for gangrene in the plaintiff's foot below the cast. Against this was presented the theory that the symptoms found in this case, namely, the appearance of gangrene above the cast, could not be produced by the pressure of the cast, but by a form of bacteria called the gas bacillus. The physicians, as usual in such cases, were in conflict in regard to the cause. The jury evidently believed in the facts, instead of the bug. The court cannot say that they were wrong.

The fact that the jury found a verdict against Dr. Rancourt only, could not be regarded as an adequate reason for setting aside the verdict. On the evidence, a finding that the other physician was acting in the capacity of an assistant could not be disturbed. As to negligence, it appeared that he warned Dr. Rancourt that he "was binding that pretty tight, and that probably he would have to remove it the next day."

The verdict was large; but the injury was also very great. The court cannot say the finding of the jury was excessive.

Remedies Relative to Mosquitoes and Malaria

(Pruitt et al. v. Bethell (N. C.), 93 S. E. R. 945. Chesapeake & O. Ry. Co. v. Catlett (Va.), 94 S. E. R. 934)

The Supreme Court of North Carolina, in the case of *Pruitt et al.* v. *Bethell*, affirms a judgment in favor of the plaintiffs, who asked for the abatement as a nuisance of a dam and pond on the defendant's land because they created conditions in which anopheles mosquitoes were bred in large numbers, which infected the plaintiffs and their tenants with germs of malarial fever. The court says that the defendant contended that a public nuisance cannot be abated in a civil action by a private individual, without showing some special damage to the plaintiff; that the state alone can abate a public nuisance in the absence of special damage to the individual, and pointed out that the jury had found that there was no damage shown contents of the fourth page gradually became statistical in character.

January, 1895, the title was changed to read, "Department of Health, City of Chicago, Bureau and Division Reports." During that year the bulletin was a two-page statistical report carrying nothing except vital statistics. The January and February, 1895, numbers had three pages of statistics showing the work of the different bureaus. One and a half pages were devoted to statistics of deaths, and the meteorological data reappeared.

In the March, 1896, number the educational page reappeared. In this number also we find charts, one of which showed the sanitary quality of the water supply by months, the other, the typhoid and diarrhea mortality rates.

In the May number, the fourth page was entitled, "Notes and Comments by the Assistant Commissioner." Dr. F. W. Reilly was the assistant commissioner. In August an effort was made to solve the midwifery problem. The fourth page of the bulletin gave the names and addresses of obstetricians willing to answer calls for assistance from midwives. In 1897, the same arrangement was followed. The June number contained an editorial on the "First Year's Work on Medical Inspection of Chicago Schools." By autumn, the bulletin had become a booster for "the healthiest large city in the world."

In 1898 the same plan was followed. The leading educational article in the July number was on "Development of Sanitary Science—the Daily Press as a Potent Auxiliary." In the fall of 1898, there was an epidemic of meningitis in Chicago. The October bulletin, in addition to the usual four pages of matter, had an additional four pages on meningitis.

In 1899, the arrangement continued the same, except that the space given to educational matter other than statistics was increasing, month by month. In June, 1899, the title was changed to read, "Department of Health, City of Chicago, Monthly Bulletin." The educational portion now occupied six pages and came first in the publication. This was followed by four pages of statistics. The August, 1899, number devoted four pages to an analysis of the water situation and demonstrated that the drainage canal was not lowering the level of the lake. After August, for the the remainder of 1899, there did not appear to be any more educational matter carried in the bulletin. The publication consisted of only four pages of statistics and was entitled, "Bureau and Division Reports." The first numbered bulletin was that of December, 1899. It was numbered Vol. VI, No. 12.

The issues from January to September, 1900, inclusive, entitled, "Department of Health, City of Chicago, Bureau and Division Reports," consisted of four pages of statistical matter. The October number again consisted of two portions. The first, termed "Monthly Bulletin," was devoted to the housing problem, and was written by Dr. A. R. Reynolds, health commissioner. The December number also had a section entitled "Monthly Bulletin." It contained a study of self-purification of streams by Dr. Reynolds.

From January to July, 1901, the bulletin was issued in two parts, "the Monthly Bulletin," educational in purpose, and a separate "Bureau Reports," statistical in character. In the latter half of that year, the title "Monthly Bulletin" was retained, but the bulletins generally consisted of four quarto pages containing statistics, mostly vital statistics, and a few editorial comments. Chicago's rather famous vaccination creed appeared for the first time in this year.

The bulletin seems to have been wholly discontinued in 1902. July 5, 1902, a weekly statement under the title "State of Chicago's Health" was begun. It appeared in every Chicago English daily paper. It varied from a half column to two columns and carried mortality statistics, a short list of the causes of death, and some educational matter. Nov. 8, 1902, the title was changed to "State of Chicago's Health, Bulletin of the Health Department," No. 45.

This plan of a weekly article in the daily papers was continued throughout 1903 and 1904. The plan was to write the article at the end of the statistical week—Saturday noon—and send it at once to the Chicago *Record-Herald*. This paper set it up and furnished galley proofs to the other papers and to the department. The department kept a file of its galley proofs. The data consisted of vital statistics and educational propaganda material. The matter was set in newspaper editorial type, and was arranged on a double column galley with the words "State of Chicago's Health" extending in large letters across the two columns.

Jan. 13, 1906, the bulletin became a four-page octavo pamphlet. The first page was given over to the title, "City of Chicago Bulletin of the Department of Health, Charles J. Whalen, Commissioner, 1906." The second page was headed, "State of Chicago's Health, Bulletin of the Health Department, week ended January 13, 1906, Vol. IX, No. 2." It contained two pages of educational propaganda material and a statement of mortality figures for the week, arranged on the short cause list. Most of these weekly bulletins consisted of two pages of printed matter, though by the spring of 1907, some of them had shrunk to one brief page. The plan followed in the department was to send the matter over to the *Record-Herald*, which set it up, furnished galley proofs to the other papers, and supplied the department with the matrix from which it printed its edition. The department paid messenger fees, cost of metal and a few incidentals.

Aug. 3, 1907, the bulletin underwent a most radical change. The title page of that number read:

> Physicians and others interested in the Bulletin may have it sent free of charge to their respective addresses on receipt of request to that effect. *Bulletin Chicago School of Sanitary Instruction, devoted to the dissemination of advice and information of the Department of Health, City of Chicago*, W. A. Evans, Commissioner, Vol. I, New Series No. 1; Vol. X, Old Series, No. 31, August 3, 1907. Published every Saturday by the School of Sanitary Instruction. Application made at Chicago, Illinois, for entry as second-class matter.

Vol. I, No. 5, Aug. 31, 1907, changed the last item to read, "Entered at Chicago, Ill., as second class matter."

The money saved on postage was used to send out an increased number of copies of the bulletin. In 1907, the department of health was incorporated with the secretary of state as an educational institution. Since that time, the educational feature of its work has always been kept to the fore. As a rule, the issues of the publication in 1907 consisted of six pages. All the space was given to educational matter except that used for contagion, morbidity tables and the mortality statistics of the week arranged on the form of short list of causes of death, prepared by the United States Bureau of Vital Statistics.

Aug. 31, 1907, the title page first bore the following:

> "Sanitary instruction is even more important than sanitary legislation," said the late Earl of Derby, himself eminent both as sanitary instructor and as sanitary legislator. This bulletin is intended for instruction in sanitary matters chiefly among the laity. Incidentally, it should help the profession by such popular education of its clientele in nontechnical phrase.

This was abbreviated, June 5, 1915, to read, "Sanitary Instruction is even more important than Sanitary Legislation."

March 7, 1908, the system of numbering was changed so that it read, "Vol. XI, Old Series No. 530," instead of "Vol. XI, Old Series No. 10," as it would have read, had the change not been made.

In the latter part of 1909, the bulletin began to be newsier and more gossipy. About this time the healthgrams for which it attained some reputation began to appear.

Sept. 30, 1911, the years old subtitle on the second page, "State of Chicago's Health" disappeared from the bulletin. In October, 1911, the title page was again somewhat changed. The offer of the bulletin free was dropped, as was the explanation of the purposes of the bulletin. It reads, "The Bulletin is issued every Saturday by the School of Sanitary Instruction. Entered as second class matter under act of July 16, 1894." The title occupied the upper third of the first page, and the reading matter the remainder.

Such are the steps in the evolution of the bulletin of the Chicago Health Department. This publication, which the press has supported and used for stories, has been a very important factor in elevating standards of health. Scoffed at a few years ago, it has served as a pattern for health department publications throughout the country. For this reason, its evolution is entitled to a place in medical history.

10. **Problem of Disabled.**—Jones is convinced that no ministry was ever created with greater responsibilities, or greater powers for good, than the British Pensions Ministry. It is in a position literally to save England after the war is won. As it has been decided that, for military reasons, soldiers after discharge and while they are undergoing training shall not be under army control, the Pensions Ministry has not the power to compel the pensioner to undergo training. It has certain powers which enable it to put pressure on the pensioner in order to enforce training and treatment. If treatment is refused, short of operation, the pension is reduced. Moreover, bonuses are given to men who train, in addition to their full pension, and if they are married separation allowance. Many pensioners will require treatment for two or more years. This treatment can be carried on while the man works or trains.

12. **Return of Power in Paralyzed Muscles.**—The operation described by Riely was not undertaken with the idea that muscle power could be restored, but as a means of mechanically aiding the patient in walking, and prevent the necessity of so much bracing. Incisions are made over the highest points of origin and over the point of insertions of the paralyzed muscle or muscles that allow the greatest deformity. Holes are drilled through the bones at these points, straight or curved, as the case requires. Then one end of heavy paraffined braided silk is passed through the hole at the origin and tied so that it cannot slip; the other end of the silk is threaded in a long bodkin-like carrier, which is passed into the muscle sheath on the side next to the skin and along the course of the muscle, out through the incision at the point of insertion. The instrument is then unthreaded and the silk passed through the hole in the bone at the point of insertion; the deformed part or parts being forced into a normal standing position, the string is drawn tightly and thoroughly tied. The incisions are closed, preferably by subcutaneous sutures, and the cast applied with the deformity in an overcorrected position. In ten days the cast is removed, the sutures taken out, and the cast renewed with the overcorrected position retained. The second cast should be left on at least three, if not four months, as a shorter time seems not to be sufficient for the holes in the bones to heal thoroughly enough not to give way or leak. Where the muscle that is to be relieved has a tortuous course, it sometimes is necessary to make other incisions at the points of some of the curves where they are too sharp to let the cord carrier pass. These cords should be as many ply as the stress put on the normal muscle would require.

In applying casts after these operations, great care must be taken to shorten the distance between the origins and insertions of all overstretched paralyzed muscles, and to increase the distances betwen the origins and insertions of all relaxed paralyzed muscles. Strong tensions on contracted active muscles should also be avoided as much as possible. This can be done best by fixing the affected parts in positions of flexion, extension, adduction, abduction, or a combination of these, as the case requires. The operation still being in the experimental stage, Riely is still uncertain just when to clip or remove the strings, even after the deformity has been overcome and power regained. As a result of past experience, it is his opinion that, in most cases, it is safe and proper to delay this removal for three years. Removal, or clipping of the strings, is a very simple procedure.

15. **Tendon Transplantation to Stabilize Hip Joint.**—Yergason suggests the transplantation of the tendon of origin of the semimembranosus muscle. This strong, flat tendon is set free by blunt dissection, as far up as possible beneath the long head of the biceps and as far down as the point at which it joins the muscle belly. At this level it is cut across. The upper end of the wound is next retracted, the biceps being drawn inward and the gluteus maximus strongly upward. Well under the outer margin of the biceps, and a short distance below the tuber ischii, the tendon of the semimembranosus is again identified and set free. The freed and transected tendon is now drawn up from beneath the biceps and the dissection continued upward to the tuber ischii. Then two thirds the distance from the top of the great trochanter to the lower border of the insertion of the gluteus maximus, the bone is exposed through a small cut in the overlying tissues. At this point a hole is drilled through the gluteal ridge (postero-external border) of the femur, in an oblique direction, from without inward and upward. The hole so made is elongated downward to form a slit, the length of which should equal the width of the tendon it is to receive. The end of the freed tendon is drawn through the opening, pulled tight, turned back, and sutured to itself. The fleshy belly of the semimembranosus, or the remnant of its tendon, is fastened to the deep surface of the semitendinosus by two or three chromic catgut sutures, and tied gently. The deep fascia is sutured and the skin incision closed. A cast should be worn for at least one month, during which time no strain should be allowed to come on the tendon. A brace from the axillae to the knee may then be substituted and, by bending this slightly, the strain of the erect posture may be gradually shifted from it to the transplanted tendon.

20 *Results of Treatment in Pernicious Anemia. A. Bloomfield, Baltimore.—p. 101.
21 Tobacco Smoke and Pulmonary Tuberculosis. A. K. Krause. —p. 106.

20. **Results of Treatment in Pernicious Anemia.**—A series of fifty-seven cases is analyzed in detail by Bloomfield with

particular reference to the comparative value of various methods of treatment. Twenty-eight cases were treated by the older methods consisting essentially of rest in bed, diet, hydrochloric acid, and arsenic. Bloomfield points out that absolute rest in bed over considerable periods of time is the most important feature of this regimen. Arsenic and hydrochloric acid are apparently useless, unless the patient is kept quiet at the same time, and cessation of improvement or relapse has occurred not uncommonly as soon as active life was resumed, despite continued drug therapy. Arsenic was used in every instance in this series either in the form of Fowler's solution, sodium cacodylate, or arsphenamin. Analysis of the cases, however, yields no data of value as to its efficacy. Achlorhydria gastrica was uniformly present and hydrochloric acid was given usually both before and after meals. In a few instances gastro-intestinal disturbances, especially diarrhea, seemed to be relieved, but in most of the patients these symptoms disappeared quite rapidly with the progress of the remission apparently regardless of any symptomatic therapy. Twenty-six patients received transfusions of blood varying in number from 1 to 17. The largest amount of blood given to one patient was 8,700 c.c., the smallest amount was 300 c.c. The single transfusions varied in amount from 300 to 900 c.c. The citrate method and the Lindeman syringe method were used most often; in a few cases indirect transfusions of defibrinated blood were given, and in one case direct transfusion was used as a preliminary to splenectomy. Six patients (23 per cent.) died. Of the twenty-two cases not transfused and receiving only general therapy, five, or 22.7 per cent., died. Transfusion was of no value as an emergency measure, nor was the immediate mortality decreased by the procedure. Following the injection of 500 c.c. or more of blood there was usually an immediate increase in the blood count and hemoglobin.

Subjective improvement was often striking, the patient saying he felt better while the blood was being injected. Among the patients who were not transfused remission set in in the hospital eight times in twenty-eight admissions, a percentage of 28.5; in the patients given transfusion there were nineteen remissions in thirty-seven admissions, or 51 per cent. It seems that in patients who are not in a stage of the disease refractory to any form of treatment, remission has come on more often when transfusion has been performed. Furthermore, the amount of blood gained runs roughly parallel to the number of transfusions and the total amount of blood given. It seems rational, therefore, if transfusion is done at all, to be prepared to inject blood repeatedly if the patient shows a tendency to respond. Single transfusions in cases refractory to other therapy led to no improvement in this series. No relation between the amount of blood given and the duration of the remission is apparent. Thirteen of the patients receiving transfusion are now dead, four are alive, while the remainder could not be traced. It is clear from Bloomfield's analysis that there was no demonstrable prolongation of life in the cases in which transfusion was employed. The patients living longest were not the ones in whom remission followed transfusion.

An analysis of the course of symptoms shows no definite variation in the groups of cases treated by different methods. Splenectomy was performed in eight instances. In one, death from pulmonary embolus occurred nineteen days after operation. Six of the remaining patients are dead. In no case was the clinical picture essentially altered, and no unusual prolongation of life occurred. In twelve cases a thorough study of the nose, throat, sinuses, teeth, gastro-intestinal tract, and lower urinary tract was made for foci of infection and, when found, these were eliminated. All these patients finally received clean bills of health from the various specialists. Most of them were given transfusions and in one case splenectomy was also performed. In none was there any feature in the subsequent course to distinguish them from the group in which foci were not found, or if found were not treated, either as to total duration of life or extent and degree of remission. It is unlikely, therefore, that such foci of infection are the cause of pernicious anemia, although it seems wise to treat them for their own sake as well as for any possible general beneficial effects which may follow.

35. **Bacteriology and Immune Reactions of Measles.**—The special points of interest in Tunnicliff's work were: the almost constant presence of a diplococcus in the blood of measles patients during the preeruptive and eruptive stages; its presence alone and in large numbers before the appearance of the eruption and alone also in a large proportion of cases at the height of the infection, and its presence at the same time in the throat, nose and eyes. Cocci similar to those found in these blood cultures were found in sections of the lung and kidney in one fatal case of measles; in the lung and bronchial lymph gland of another, and in the gangrenous tongue of a third. They appear singly, in pairs and chains. Some are found inside of leukocytes. The cocci in these sections varied considerably in size. Similar blood cultures were made from ten rubella patients. A fairly large diplococcus was observed in the anaerobic cultures in seven of these ten cases. A diphtheroid bacillus was isolated twice from anaerobic cultures. Throat smears and cultures on aerobic blood-agar plates from six cases showed diplococci similar to those isolated from the blood. Various immunity tests have been made with the cocci isolated from rubeola and rubella to determine if any antibody reaction could be demonstrated. So far opsonins have been the only antibodies found in any appreciable amount. The serum of twelve measles patients was examined, in six only once as the eruption was beginning to fade, in six usually daily throughout the course of the disease. Four of these serums showed a negative phase of one, two, two, and five days' duration, respectively. A distinct rise in opsonins for the measles organism occurred in each case as the symptoms subsided and the eruption disappeared. This rise lasted from one to four days. The point of opsonic extinction for normal blood was 1:30; for measles serum 1:15 during the negative phase and from 1:60 to 1:340 during the rise. The various strains isolated from the blood, throat, nose, eye and ear of measles patients gave similar results.

36. **Toxicity of Pneumonic Lungs.**—Salt solution extracts of pneumonic lung in the stage of gray hepatization were found to be more toxic for animals than similar extracts of normal lung tissue. The method of extraction influenced the toxicity of both extracts. Lethal doses of extracts of both pneumonic and normal lung injected intravenously usually produced anaphylactic symptoms. Sterile extracts of pneumonic lung in dogs removed forty-eight hours after intrabronchial insufflation of virulent pneumococci, were more toxic than similar extracts of lung consolidated by intrabronchial insufflation of sterile aleuronat, and both were more toxic than extracts of equal weights of normal dog lung. The toxicity of extracts of normal and pneumonic lung is decreased by heating, drying and filtration through Berkefeld filters. Extracts of human pneumonic lungs in gray hepatization were frequently hemolytic for guinea-pig cells, whereas similar extracts of normal human and dog lungs and of dog lungs consolidated from intrabronchial insufflation of virulent pneumococci and sterile aleuronat, were generally nonhemolytic. The hemolytic activity of these extracts was neutralized by antipneumococcus serum as well as by normal rabbit serum; reduced by heating and drying, and usually completely removed by porcelain filtration. One extract of a human pneumonic lung in gray hepatization was found to partly neutralize the agglutinating activity of an antipneumococcus serum. The nature of the toxic and hemolytic substance or substances in extracts of pneumonic lung is unknown; it is probably allied with the protein fractions and may be partly responsible for the production of the various systemic symptoms of lobar pneumonia ascribed to toxemia.

37. **Action of Quinin, etc., on Pneumotoxin.**—The following summarizes the authors' work: Pneumococci when dissolved in sodium choleate liberate a preformed endocellular toxin which is lytic for erythrocytes. Different preparations of the pneumotoxin vary considerably in their toxicity for guinea-pigs, mice and rats. The hemolytic power of the pnemotoxin was inconstant and not always concomitant with the degree of toxicity. Quinin and urea hydrochlorid, ethylhydrocuprein hydrochlorid, and other derivatives of cinchoma were found to exert no influence on either the toxicity or the hemolytic activity of pneumotoxin. Therapeutic doses of quinin bisulphate, quinin hydrochlorid and particularly quinin hydrobromid prolonged to a recognizable extent the lives of animals receiving one minimum lethal dose of pneumonic lung extract. Quinin and urea hydrochlorid and ethylhydrocuprein hydrochlorid had slight inhibitory effect on the hemolytic activity of the lung extracts when large, hemolytic doses of the drugs were used. Quinin hydrochlorid, quinin hydrobromid, quinin bisulphate, and hydroquinin hydrochlorid behaved in a reverse way, exhibiting marked inhibition in nonhemolytic doses and no inhibition in hemolytic doses. Neither pneumococcus protein nor pneumonic blood was found to have any neutralizing action on the toxicity of quinin salts for animals. Neither the clinically beneficial action of cinchona derivatives in the pneumonias nor the increased quinin tolerance of pneumonia patients receives elucidation from the experiments reported; the results being largely negative.

38. **Chemotherapy of Experimental Pneumococcus Infection.**—The ordinary soluble salts of mercury and numerous new mercurial compounds were found by Kolmer and Steinfield to be without appreciable effect in prolonging the lives of mice infected with a dose of Type I pneumococcus culture lethal within seventy-two hours. The results of their experiments indicate that ethylhydrocuprein hydrochlorid by subcutaneous injection in doses without protective value, usually increase the protective value of antipneumococcus serum Type I in a slight but definite manner in severe infections of mice and rats with homologous pneumococci. Several of the commoner compounds of quinin, as quinin and urea hydrochlorid, quinin bromid, and quinin chlorohydrosulphate, given subcutaneously in doses without any appreciable influence on severe and fatal pneumococcus infections, occasionally increase the protective power of antipneumococcus serum but to a lesser extent and less regularly than ethylhydrocuprein hydrochlorid. Ordinary salts of mercury subcutaneously did not increase the protective value of antipneumococcus serum; several new synthetic compounds of mercury were generally without effect on the protective power of the serum in severe experimental infections.

62. **Study of Successful Vaccinations.**—Kremers' investigation has convinced him that the method of incision is the only vaccination method which should be used in the military and naval services. It should be the method of choice for all vaccinations. The cross scarification method gives a slightly higher percentage of primary "takes" than the incision method and a reduced higher percentage of total "takes" (revaccinations included) in unprotected persons. Of the total "takes" 87.1 per cent. were secured in 257 unprotected men by the incision method against 92.4 per cent. in 225 unprotected men by the cross scarification method. The percentage of "takes" secured by the incision method is sufficient when carefully done to prevent epidemics of smallpox. The slightly higher percentage of "takes" secured by the cross scarification method is offset by the increased number of infections which follow this method.

103. **Renal Tuberculosis.**—Bugbee's analysis shows that while the active tuberculous process in the kidney has been arrested and walled off, still this is not the rule, the lesion being progressive. Even when arrested, a kidney the site of poorly drained cavities is a menace to the system. Therefore, nephrectomy for unilateral renal tuberculosis is the proper treatment. With the means at hand by which we can often make an early and accurate diagnosis of renal tuberculosis, and with statistics showing that 75 per cent. of the cases of unilateral infections are cured by nephrectomy, the tendency is to be too optimistic as to the future in these cases. They should all report regularly, be watched and treated as cases of general tuberculosis.

105. Abstracted in The Journal, July 14, 1917, p. 144.

111. **Entrance of Air into Mediastinum.**—In the treatment of this condition Buford feels that free ventilation of the room and oxygen are indicated, that possibly digitalis products are beneficial. In the graver cases venesection offers us more relief than anything else. If after venesection there is still no relief, incision of the anterior mediastinum has been recommended in somewhat parallel conditions. The wisdom of this is debatable because it is possible that instead of relieving tension more air might be admitted and the symptoms aggravated. This question needs to be settled by animal experimentation. If incised the edges of the wound should be kept apart by stiff rubber drains or other methods, but at no time should gauze be used for that purpose because its meshes fill with blood and soon plug the wound. It also remains to determine by experimentation what, if any, relief may be obtained by very slow aspiration of the anterior mediastinum through needle puncture.

117. **Modification of Ahlfeld Method.**—The modification of the Ahlfeld method proposed by Thoms may be described as follows: The patient is placed in the lithotomy position for the ordinary vaginal examination. The examination may be conducted either vaginally or rectally. If the head is high up and cannot be reached per rectum the vaginal route becomes necessary. If, however, the vertex can be palpated at all per rectum the rectal route becomes preferable not only on account of the lessened danger of infection but because the examining finger is in the extension of a line corresponding to the axis of the fetus in utero.

120. **Treatment of Cystocele and Uterine Prolapse.**—Briefly Watkins' procedure consists of a wide incision anterior to the cervix, free separation of the herniated part of the bladder, closure of the hernial opening by circular sutures, restoration and fixation of the urethrocele, and perineorrhaphy are essential features in the operation. Amputation of the cervix, trachelorrhaphy, plastic surgery on the broad ligaments, and vaginal fixation of the round ligaments are adjuncts which can be utilized as necessary.

3. **War Edema and Bilateral Parotid Enlargement.**—Park says that this is a condition so peculiarly German that to give it an English name would accuse us of want of chivalry. Over and above this, to speak of the condition as "war edema" is incorrect; it is not war but purposeful underfeeding that is the primary cause. It is a famine edema, not a war edema. This disease occurred among the prisoners of all nationalities who were fed on German rations only. Kriegsoedem is the result of underfeeding, especially in fat and protein. It can be cured easily in the early stages by sufficient diet. When well established it is frequently complicated by a colitis, when the mortality is high. The condition commences as slight edema of the feet and legs, disappearing when the patient is recumbent. Patients are seldom admitted to the hospital in this stage, although proper feeding with rest in bed would completely restore them in a few days. The usual type found in the hospital presents a massive edema of feet, legs, thighs, and scrotum, with some puffiness under the eyes. Ascites is common. The patient is pale and dull; indeed, the appearance is strikingly like that of a case of parenchymatous nephritis. There is extreme muscular wasting and weakness. Dyspnea is only present on exertion, except when there is hydrothorax. The heart is slightly enlarged; the action is regular, but usually slow; the muscle tones are poor, and the second aortic sound is not accentuated. Blood pressure is low. There are commonly many moist râles in the lungs posteriorly, especially toward the bases. Uncomplicated cases are afebrile. In the most serious cases there is a general anasarca, the chest and abdominal parietes are edematous, and all the serous sacs become filled with fluid. In one case Park removed 15,000 c.c. of watery fluid from the pleural sacs in a series of six punctures during two weeks. In a few cases paracentesis abdominis was done. Hydropericardium was common, but never extensive enough to require withdrawal.

Park also saw some twenty cases of a condition of enlargement of the parotid glands which was always bilateral. The enlarged glands were at no time hard or painful, but rather they were soft and doughy, the swollen regions being easily pinched between the finger and thumb. The condition was afebrile; in no uncomplicated case did Park encounter rise of temperature in association with it. It was never accompanied by orchitis, and it tended to persist indefinitely.

9. **Intravenous Quinin Acid Hydrobromid in Malaria.**—Knowles claims that the intravenous administration of quinin in concentrated solution is the quickest and surest method of immediately cutting short a febrile attack of malaria. It appears to be a perfectly safe method, and is infinitely preferable to intramuscular injections from every point of view. It cannot, however, be relied on to exterminate the malarial parasite from the patient's system, and should be supplemented either at the time of that attack or subsequently by an oral course of quinin. The special rôle of the intravenous method is in bilious remittent fever, in algid or comatose cases in delirium, and in relapses in old standing malarial patients. In cases of malaria, heptic deficiency is often a prominent feature, as shown by the frequency of the urobilin finding in the urine; while no matter how much quinin be given orally, gastric irritation may limit the amount which enters the circulation. Knowles, however, prefers its use as a routine measure during the febrile attack in all forms of malaria, either with or without simultaneous administration by the mouth. Even when no quinin can be given by the mouth the fever can be at once terminated by intravenous quinin; while other drugs are given orally to combat gastric and hepatic irritation. By the intravenous technic the drug reaches the circulation instantly in a known dose, its full force is at once exerted on the malarial parasites in the blood stream, while further, the excretion of drugs, after intravenous administration, is more rapid than after dosage by the mouth.

There is quite a sufficient volume of evidence now available to justify the routine and extended use of quinin intravenously. In many instances intravenous quinin can be depended on to save life. The most suitable solution is probably a 5 to 10 per cent. solution of the acid hydrobromid in normal saline, though further work is required on quinin urethane and colloidal quinin. For an adult five consecutive daily injections of from 7 to 10 c.c. are recommended. In a critical case a gram should at once be given intravenously. The injections should, so far as possible, be so timed as to coincide with the rising temperature or with the rigor. The method has been used in advanced pregnancy and also in a case of excessively severe dysmenorrhea without causing any distress to the patients.

24 *Management of Neurasthenia and Allied Disorders Contracted in Army. J. Collie.—p. 2.
25 Civil Sanitation and War. E. W. Hope.—p. 18.

24. **Neurasthenia and Allied Disorders in Army.**—Neurologic centers have been established both by the French and English war departments immediately behind the fighting line. Here quick returns are the order of the day. The atmosphere in which a shell shocked soldier is treated, Collie says, is second only in importance to the personality of those who are to treat him. In these front line neurologic centers the treatment is more intensive, but the feature which distinguishes it from those employed at home is that the cases are taken, as it were red-hot from the battlefield and are moulded by the strong will of those specially selected for their treatment. Frequently men are returned to the fighting

line in two or three weeks. There is a special shock hospital for each army area. They are placed near the clearing hospitals, and are staffed by specially selected medical officers under the superintendence of a neurologist of repute. Here the case is investigated thoroughly, and if it is found that the man is not likely to recover soon he is sent to a base hospital, from which in time he may be transferred to England. Numbers of the men treated at these special hospitals are found after one, two or three weeks' treatment to have sufficiently recovered to be transferred to a local convalescent camp, where attention is specially paid to them as convalescent neurasthenics. Appropriate exercises are prescribed, and later on football and competitive games of skill are encouraged. In these special shock hospitals definite data of the reflex responses and other phenomena are being collected. In the advanced stations for dealing with these functional conditions the percentage of cure is very high, and the duration of the conditions is remarkably short. An immense proportion of this class of case is curable. Failures depend on the stubbornness, lack of will power, or refusal of further treatment by the patient.

A thorough physical examination followed by a definite assurance that no organic disease is present is a good foundation for the cure of functional disease. Reeducation is the keynote of the treatment for shell shock. A healthy and invigorating environment is everything. Massage, electricity, persuasion, occupation, light graduated work, fresh air, good wholesome food, and above all a healthy outdoor environment are essential adjuncts. The psychotherapeutic method of treatment has been found by experience to be wonderfully effective, provided only it is in the right hands. Persuasive conversations should be systematically arranged for, in which the patient and physician can have quiet talks, so that the man is led by tact and guarded sympathy to lay bare what is, as it were, at the back of his mind. Nothing in the nature of so-called psychanalysis is necessary. All patients should be isolated during the earlier part of their treatment. The calm restfulness of solitude has a peculiar effect in allaying irritability, and prevents morbid introspection. Isolation is not solitary confinement; a nurse is in frequent attendance. Electrical treatment for these cases is of value, but the stoutest advocates of this method will not deny that the effect is intimately associated with the mysteriousness of the electric current. Work in one form or another is the only salvation for those who are suffering from functional nerve disease.

In spite of the treatment afforded and the large number of cures effected, it is obvious that a very appreciable number of men have been so incapacitated by shell shock and kindred nerve injuries that they are not fit for any further military service and receive their discharge. There is a large residuum who have not yet recovered, who are wholly unable to earn a livelihood, and who obviously cannot recover without very specialized treatment. At the request of the Minister of Pensions Collie has undertaken the organization of homes of recovery in different parts of the country for the institutional treatment of ex-soldiers of this class. Two institutions, one accommodating 100 patients and the other fifty, have been opened, one in London and the other in Belfast, and a third is being arranged for in Manchester. The principal methods adopted in these remedial homes are: 1. An attempt is made to gain the confidence of the patient and teach him to believe that he will recover, and continuous and painstaking efforts are made to persuade him to adopt an optimistic frame of mind. 2. The application of the usual remedial methods, such as massage and electricity. 3. Outdoor work and recreation are insisted on.

29 Obliterating Arteritis. Carpentier.—p. 112.

27. **Disappearance of Murmurs During Paroxysmal Tachycardia.**—Bard reports two cases which warn that even the most pronounced of the orificial murmurs are liable to disappear during an attack of paroxysmal tachycardia, and thus mislead the examiner. Inorganic murmurs often accompany the continuous tachycardia with exophthalmic goiter, as also with simple nervous palpitations. But these inorganic murmurs do not belong to the habitual clinical picture of paroxysmal tachycardia. With this the heart beat is much faster than with ordinary tachycardias. He has witnessed the subsidence during the paroxysmal tachycardia not only of the signs of mitral stenosis but also the murmur of aortic insufficiency and even the murmur from perforation of the interventricular septum in an extremely characteristic case of Roger's disease. In examining the patient therefore, more than one examination is necessary, watching for attenuated signs of masked lesions. In one of the two cases described the man of 22 had no trace of a murmur during the several days of the paroxysm of tachycardia although he was known to have a perforation of the septum. In the other case the pronounced aortic murmur disappeared as the tachycardia set in.

37 *Kala-Azar in Children in France. M. Labbé, Targhetta and Ameuille.—p. 288.
38 *Meningeal Hemorrhage in War Pathology. G. Guillain.—p. 290.

30. **Bread Made from Grain Without Grinding.**—See Paris Letter, p. 1391.

31. **Malarial Tremor.**—De Brun relates that tremor is noted in nearly every case of secondary malaria in his service. The tremor sometimes is so intense that it interferes with the man's work as a draftsman or painter and with writing and playing an instrument, but usually it is too slight to attract attention. The tremor varies in its intensity; in two of his cases, exaggeration of the tremor warned of an impending malarial attack. In the majority of cases it seems to be the expression of a toxi-infection, but in others some organic lesion is evidently responsible.

33. **Spots in Candled Eggs.**—Martel is chief of the Service vétérinaire sanitaire, and he here reports bacteriologic study of the spots seen in candling eggs. This does not reveal any change in color or taste, or slight infection of a fresh egg acquired during its development. But otherwise the findings with candling can be usually relied on.

36. **Autonomic Pathology of Emotivity.**—Dupré's views were summarized in de Fleury's article, of which an abstract was given, April 20, 1918, page 1194.

37. **Kala-Azar in Children.**—The two children presenting typical leishmaniosis were refugees from Serbia, but the disease had developed eighteen months after their arrival in France. They lived at Nice. The longest incubation known was in a 6 months babe. Leishmaniosis in dogs is known on the French coast of the Mediterranean.

38. **Meningeal Hemorrhages in War Pathology.**—Guillain emphasizes the danger of overlooking meningeal hemorrhages, especially with shell shock, etc. Besides the classic symptoms, headache, stiff neck, bradycardia, etc., meningeal hemorrhage should be suspected with cerebral excitation accompanied with mental confusion, a contralateral flexion reflex when pressure is applied to the femoral quadriceps, true defense reactions like those of the frog, pupil disturbances, and massive albuminuria in some cases. There may also be a sallowness from the local hemolytic processes. The products of the hemolysis may exert further a toxic action on the nerve centers and nerve roots.

43 *Streptococci in Wounds. L. Ramond and C. Vergelot.—p. 142.

43. **Improved Technic for Cultivating the Streptococcus.**—Ramond and Vergelot comment on the importance of early detection of the streptococcus in war wounds as contraindicating primary suture. In 142 cases they found the streptococcus at 195 examinations, and invariably the course of the wound corresponded to what was anticipated from the presence of the streptococcus. The characteristic chains appear earlier and more certainly when Sacquépée's sodium albumin is added to ordinary bouillon. The streptococcus proliferates in this mixture before other bacteria, sometimes in three hours, and almost always in six, showing the typical chainlets. Using three to five loops instead of one, while reducing the culture medium to 0.5 c.c., aids further in hastening the development of the culture. The Sacquépée sodium albumin is prepared by mixing white of egg with three times its volume of distilled water, stirring constantly but without beating to a froth. To 1,000 c.c. of this mixture is added 5 c.c. of a 10 per cent. solution of sodium. After distributing in tubes it is sterilized at 110 C. for twenty seconds. One part of this, mixed with four parts of ordinary bouillon, is distributed in tubes in the proportion of 1 c.c. of the fluid to a tube 1 cm. in diameter. About 0.5 c.c. of the fluid is inoculated with three or five platinum loops of pus or serous fluid. The tube is kept at 37 C. and examined under the microscope the third and sixth hours or oftener. Positive findings were obtained in three hours in 80 per cent. of the positive cases; in 90 per cent. in less than six hours, and in 99 per cent. by the next day. They always made parallel tests with other culture mediums.

46 Focus of Autochthonous Malaria. P. Ravaut.—p. 232.
47 *Subacute Rat-Bite Disease. P. D'Halluin and J. Fiévez.—p. 234.

44. **Crippled Lungs.**—Labbé and Arié remark that the war has compelled us to regard the healing art from a new angle, namely, that we now have to consider first of all the future utilization of the man in military service and in civilian life later. They discuss here the men who are "lame," not in their legs, but in their respiratory passages. Before the war, these men sought easy, sedentary occupations, and their chronic bronchitis, suspicious apical findings or emphysema were not regarded as actual sickness; they merely wore a muffler on their way to work, and attended to business as usual. Under the vicissitudes of military service they have to be sent again and again to the infirmary for bronchitis, etc. The anatomic lesions in these cases are so minute that the complaints seem out of all proportion to them, and appreciation of the actual functional capacity of the man is a difficult matter. Only the regimental physician, seeing the man under various conditions of walking, running, and other military exercises, is able to estimate what the man can actually stand. The regimental physician should always be consulted in these cases. A change of service to the heavy artillery or aviation work, relieving the men of marching and much carrying, may be all that is necessary for these "air passages cripples." With weakness and anemia, the auxiliary service may be preferable. The lesion in these cases is not progressing, and there is every chance that exercise will improve instead of aggravating the condition. With active tuberculosis, on the other hand, even smaller lesions call for dismissal from the service, as any overexertion is liable to rouse or accelerate the progress of the bacillary lesion.

45. **Transfusion of Citrated Blood.**—Rieux has simplified the technic for transfusion; among other points, by using a trocar-needle to draw the blood without first exposing the vein. This renders the procedure so insignificant that several donors can be tapped for the needed amount of blood, instead of taking it all from one donor.

47. **Rat-Bite Disease.**—The woman of 49 had been bitten in a finger by a rat, and the glands in the axilla and above the clavicle became enlarged, with attacks of fever recurring during six months, with neurasthenia and loss of appetite. Under serotherapy (*sérum névrosthénique*), and 0.005 gm. sodium arsenate by the mouth, daily, the symptoms gradually subsided. The intervals between the febrile attacks were remarkably regular, practically always six and a half days, or multiples of this. Toward the last, urticaria developed; this does not seem to have been noted before in the European cases, but it is further proof of the identity of the disease in Europe and Japan. Quinin had absolutely no effect, and the recovery under two or three months of the arsenic may have been merely the self-limitation of the subacute infection. The disease is known after the bite of a weasel or ferret, and even from a mere sojourn in a rat infested environment (Dick and Rutherford).

51 Syphilis in Natives of Morocco. Lacapère.—p. 146.
52 The Abuse of Milk in Children's Diet. J. Comby.—p. 150.

48. **Resisting Power of Blood Corpuscles.**—Chauffard and Huber tested with various isotonic salt solutions the blood corpuscles from forty-four persons. Their findings confirm anew the immense importance of the phenomena of osmosis in the life of the cells, and the folly of regarding isotonic solutions as physiologically interchangeable. Too many factors are involved, and even although the isotonic osmotic tension is a protection for the living cell, this protection is only relative, and injurious chemical action is always possible. Of all the solutions tested, freshly prepared Ringer's fluid seemed to be the least harmful for the cells.

49. **Rôle of the Periosteum in Formation of Bone.**—Leriche and Policard declare that the periosteum should be regarded as a physiologic entity rather than from the standpoint of anatomy. Correctly managed, we can almost create bone at will from the periosteum. The balance and coordination between bone and periosteum are like those between the derma and the epidermis. Repair of bone requires always the cooperation of bone tissue and of the neighboring soft parts: It depends on the periosteum physiologically understood. There is no specific bone-producing layer between the bone and the fibrous stratum, and bone is not secreted, in the strict sense of the term. It forms by the junction of bone and the fibrous tissue, represented by the periosteum, the outer layer of the bone participating, as they show by microscopic views of newly proliferated bone. The new bone grows out like a tumor in the direction of least resistance, but there can be no bone growth from the periosteum unless the superficial layers of bone have been scraped off with the periosteum. In all cases of subperiosteal resection of bone, the detached periosteum appears as if covered with minute grafts, the grafts formed of vascularized bone scraps, the growth of which is limited by the fibrous tissue of the periosteum itself.

64 *Paradoxical Ankle Reflex as Sign of Organic Disease. R. Bing.—p. 465.
65 *Operative Cure of Cancer at Junction of Esophagus and Cardia. E. Bircher.—p. 467.

64. **The Paradoxical Ankle Reflex with Organic Disease.**—Bing found the reflex described in fourteen out of nineteen cases of organic spastic paralysis, while it was never present in 200 cases of psychoneuroses or nonspastic paralysis or in the healthy. The leg of the reclining patient is placed as for eliciting the foot clonus, that is, with moderate flexion in hip and knee joints, and the leg is lifted from the bed. The examiner's hand brings the ankle into slight extension (dorsal flexion), slightly stretching the Achilles tendon. Then with a broad and heavy reflex hammer a blow is struck at any point along the line of the ankle between the tips of the internal and external malleoli. With positive findings, there is a strong contraction in the gastrocnemius muscle while there is plantar flexion of the foot, at least as pronounced as with the Achilles tendon reflex. It is immaterial whether the blow hits the tendon of the tibialis anticus, extensor hallucis longus, or extensor digitorum communis. With a negative response there is no spasmodic contraction of the muscle, or only a weak extension spasm (dorsal flexion). This reflex was associated with the Babinski reflex in seven cases, and with foot clonus in seven. In one case of cerebral syphilis and three of war wounds of the cortex, this paradoxic or inverted reflex was the only pathologic reflex phenomenon that could be elicited.

65. **Cancer at Junction of Esophagus and Cardia.**—In analyzing his two successful cases and previous mishaps in others, Bircher has become convinced that the abdominal route offers the only guarantee of success. It is possible to draw the esophagus down into the abdominal cavity for from 4 to 7 cm. Witzel has drawn it down for 10 and even 14 cm. Bircher sutured the esophagus to the stomach according to the principles of a gastric fistula, Kader or Witzel, covering the exposed esophagus completely with peritoneum. A fistula into the stomach enabled the patients to be given nourishment from the first. One patient is still in good health over a year since the operation. The other after a period of comparative health succumbed to his valvular disease. In a third case, all was going well till the tenth day when—contrary to orders—food was given by the mouth. Vomiting followed, and the wound around the gastric fistula tore open, with fatal infection. Necropsy in these two cases showed ideal healing of the suture between esophagus and stomach.

[illegible] [illegible] the Liver and Insomnia. P. F. Arullani.—

70. **Liver Dulness in Typhoid.**—Lesieur called attention recently to an area of subdulness at the base of the right chest, which he called retrohepatic subdulness, and claimed it to be an early sign of typhoid. He found it pronounced in 80 or 90 per cent. of 300 typhoid cases, and others have confirmed this finding. Piazza stated that the area of dulness over the liver in the back extends normally from 3 to 5 cm. toward the left, but in typhoid it extends 6 or even 8 cm. to the left. Campani and Bergolli found this sign only in 40.7 per cent. of 105 typhoid patients, while on the other hand it was found in other morbid conditions. The probable explanation for it is some congestion in the lung, from reduced tonus of the vessels, plus the disturbance in the circulation in the region from the enlarged liver. The right lung rests on the solid base of the congested liver.

71. **The Liver and Insomnia.**—Arullani reports the case of a man of 52 who was under treatment for rebellious and extensive eczema. He had suffered for two years from a tendency to insomnia, but nothing else pathologic was known except that the liver was enlarged and the urine contained urobilin. Comparison of the day and night urine confirmed that the insufficiency of the liver became more pronounced at night, a cerebral toxemia resulting, this explaining the insomnia. The eczema was also traceable to the liver insufficiency, as was proved by the complete recovery under treatment addressed to the liver. (The therapeutic measures are not mentioned.)

77 *Bacillary Diarrhea. M. Ghiron.—p. 317.
78 Technic for Sending Blood for Analysis. S. Scigliano.—p. 319.

72. **Fate of Metal Scraps in the Tissues.**—Calandra has noted small zones of sclerosis of a grayish color, as the relics of a small scrap of metal in the tissues. The metal has disintegrated, but the gray sclerosis may cast a shadow suggesting a foreign body. He urges the importance of removing all the scraps of metal, as this metalization of the tissues can do only harm.

77. **Bacillary Diarrhea.**—Ghiron describes a bacillus found in sixty cases of diarrhea, which he cannot class with any of the known types.

81 Traumatology of the Liver. E. Aievoli.—p. 222.
82 Scurvy or Hemorrhagic Diathesis? S. Fichera.—p. 224.

79. **Hemorrhagic Purpura.**—Giugni describes the endemic-epidemic appearance of hemorrhagic purpura, suggesting scurvy, among the troops on the firing line in 1916. He compares the experiences in this line at various points, and discusses whether the mountain climate, the emotional stress acting on glands with an internal secretion, and defective diet may have brought on the disease, or whether we can accept as the cause the spirochete found by Siccardi in various hemorrhagic states.

83 *Malignant Endocarditis in Children. L. Morquio (Montevideo).—p. 129.
84 Scabies in Children. E. A. S. de Aja.—p. 145.
85 Abscess in Lung of Child. G. Gamero.—p. 157.

83. **Malignant Endocarditis in Children.**—Morquio analyzes three cases in two girls and one boy, 8 and 5 years old, with the necropsy findings in one. These cases emphasize anew the vague and confused clinical pictures in such cases, simu-

lating typhoid, etc. In each there was embolism, right hemiplegia and death with the clinical picture of septicemia. Acute rheumatism was known in two and typhoid in the third case. In one case the endocarditis developed with pain and swelling in the right knee and ankle. Then more joints became affected and heart symptoms developed, with fever and death in four months. In the second case, gastro-intestinal symptoms were first noted in the previously healthy child, then the endocarditis symptoms, and death in two months. The youngest child had acute articular rheumatism for about a week. The mother then died of typhoid and the child developed right hemiplegia soon after, and a typhoid and endocarditic state, with death four months after the first warning symptoms of the acute rheumatism. No physician was called in until the mother's illness.

98 Modification of Anterior Gastro-Enterostomy. R. Finochietto.—p. 88.
99 The Balance of Fluids in Typhoid Fever. V. Hutinel and E. Beretervide.—p. 96.

95. **Prophylaxis of Tuberculosis in the Navy.**—Castillo and Lopez relate that vaccination against typhoid and preventive measures against venereal disease have been compulsory in the Argentine navy for nearly three years, but nothing special has been done for prophylaxis of tuberculosis, and yet the mortality from this is higher than in other navies and in the army. The mortality from tuberculosis in the army in 1915 was 2.36 per thousand, but in the navy, and preparatory institutions, it was 12.40 per thousand and in the enrolled men, 5.35 per thousand. Among the new recruits (*conscriptos*) it was 19 per thousand. For pulmonary tuberculosis alone in the navy, in the enrolled men, the figures were 4.75 and among the new recruits 9.30. In the navies of Germany, Great Britain and North America the figures were, respectively, 2.40; 3.20 and 2.30, and in the Argentine army 2.36. Analysis of the data shows that the sudden change of life and the excessive physical exercise to which the new recruits are subjected cause the flaring up of apparently extinct or latent tuberculous processes in the conscripts. An initial hemoptysis in the month after joining the force is certainly the work of the excessive physical exercise following on a previously sedentary existence. Others show brief periods of fever, evidently from the unaccustomed physical overexertion. In prophylaxis, a six months' course of preliminary training in hygiene and gymnastic exercises might reenforce the defensive powers of those fit for the service, and weed out those with progressive lesions. The latter should not be returned at once to their homes, but special sanatoriums for the navy should be organized. The need for this has been long recognized by the medical officers of the navy, but no steps have been taken in the matter as yet.

96. **Unilateral Hypersecretion of Saliva.**—The parotid gland was much enlarged and the saliva spurted from the duct of Steno in a fine jet when the gland was compressed. The flow was so profuse that the man was unable to work, while he suffered constantly from thirst and headache. The flow of saliva during the night filled a basin. Under bromids the flow was transiently less profuse. On the assumption of reflex hypersecretion from irritation of the auriculotemporal nerve, this nerve was twisted until its finest fibers were torn. The technic was that applied by Leriche, Dieulafé and Aigrot to reduce hypersecretion from various causes. The nerve was reached back of the condyle of the lower jaw. The operation was comparatively insignificant but proved a complete success, as also in two other cases with annoying hypersecretion with cancer in tongue or cheek.

107 *Radium Treatment of Cancer of Larynx. R. Botey.—p. 289.
108 Technic for Removal of Uterine Fibrosarcoma. V. Aza.—p. 292.

107. **Radium Treatment of Cancer of the Larynx.**—Botey gives an illustrated description of his method of radium intubation for malignant disease of the larynx. He expects to present at the coming national Spanish Medical Congress a detailed report of his experiences with this *intubacion radifera* during more than two years, to date. As a rule, patients with cancer of the larynx absolutely refuse an operation, while the sensitiveness of the larynx region, the reflexes set up so rapidly, forbid the direct application of radium such as has proved so successful in uterine cancers. He introduces the radium inside a small tube which fits into a tracheotomy tube, if stenosis requires a tracheotomy; if not, inside a tube something like an ordinary intubation tube. The radium tube is arranged with a lead shield so that the mucosa is protected everywhere except at the point of the cancer. Owing to the sensitiveness of the region, he gives small doses and only for 3, 6, 12 and 18 hours. Exacerbations, recurrence and metastasis are of course more frequent under radium treatment than after operative removal, but he has a number of apparent cures which justify the radium intubation treatment when radical removal is not possible.

109 *Utilization of Anal Sphincter in Correction of Incoercible Vesico-Vaginal Fistulas. A. Turenne.—p. 41.
110 *High Uremia. F. Cortabarria.—p. 59.
111 *Drainage for Puerperal Endometritis. J. Infantozzi.—p. 63.
112 Appendicular Syndrome with Menstruation. H. Platero.—p. 71.

109. **Utilization of Anal Sphincter in Treatment of Vesicovaginal Fistulas.**—Turenne reports a case of destructive vesicovaginal fistula for which he had done six operations—none giving more than brief temporary relief. Conditions were such that none of the ordinary procedures were applicable. He then implanted a Murphy button in the wall of the rectum and passed a retention catheter through it (Petzer No. 28) thus diverting the urine through the anal sphincter. The urethra and vulva were sutured to close them, as also the last traces of the external fistula. The woman has been on the operating table under an anesthetic nine times in all, but the news from her nearly a year since the last operation were that she has increased much in weight, the stools are normal and she can hold her urine for an hour or hour and a half, and there are no pains anywhere, no fever, and the urine is limpid; the only trace left of anything abnormal is that occasionally there is a little blood in the urine. An illustration shows the details of the simple intervention. The button and the catheter were removed on the tenth and fourteenth days. In conclusion, Turenne remarks that after the urine has been diverted in this way, attempts to close the vulva and vagina may fail again and again, as in this case, but with patience and perseverance this is finally accomplished. The anastomosis should be made close to the internal margin of the internal sphincter. The button is not necessary if one is an expert in plastic surgery of the inferior genital passages, but otherwise it materially simplifies matters. This method is indicated when there is extensive destruction of tissue, including the loss of the neck of the bladder.

110. **High Uremia.**—Cortabarria's patient was a woman under treatment for abortion. There was jaundice for six days, with vomiting, chills, and epistaxis, somnolency, and prostration, purulent lochia and irregular fever. The blood showed 2,140,000 reds; 46,000 whites, and 6.40 per thousand urea, which increased to 6.66 just before death. In the urine the figures were 7.04, 17.8 and 16.26 on corresponding days.

111. **Permanent Drainage for Puerperal Endometritis.**—Infantozzi extols the fine results he has obtained in ten years of experience with puerperal endometritis draining the uterus with a glass drain left permanently in place, supplemented by instilling some antiseptic solution. For this he usually prefers 20 or 40 c.c. of glycerin containing 5 per cent. turpentine or creosote, introducing it with a syringe and catheter. Lately he has been applying the Carrel method which has the advantage of being more fluid and permitting introduction of 100 c.c. of the fluid. He denounces copious irrigation of the uterus as exposing to grave dangers, and also protests against the use of the curet for the same reason. Digital evacuation of relics of the pregnancy is effectual if well done or a shallow (Roman) spoon might be used. Rubber tubes get kinked or clogged; a glass tube answers the purpose better. The only danger with this treatment is that bacteria may be carried up from the vagina into the uterus, in introducing the tube, but this danger can be warded off with the appropriate precautions.

116 *Buttermilk. E. Fynn.—p. 161.
117 *Prophylaxis of Infectious Diseases at Buenos Aires. E. R. Coni.—p. 162.

115. **History of Drugs.**—Dominguez calls the customs and traditions in respect to drugs, pharmaco-ethnology. He traces its history through the ages from the mythology of ancient Greece to date, describing the use of herbs, incense and oils in rituals, etc., and the use of plants, grains and herbs in the preparation of beverages and liquors. He enters into the details of the production of the native liquors of Central and South America, and mentions a drink used in Siberia made from the *Amanita muscaria,* a poisonous mushroom.

116. **Buttermilk.**—Fynn expatiates on the advantages of buttermilk in infant feeding at times. If the children dislike it, the intervals between feeding can be lengthened until they have more appetite; they usually learn to like it. He makes a practice of giving a castor oil purge before commencing the buttermilk, as otherwise the tendency to constipation that follows its use may cause absorption of toxins from the bowels. For infants over 15 months old, he gives it with 10 per cent. flour. At weaning he gives buttermilk associated with skimmed milk, gradually adding whole milk if all goes well. Dilution of whole milk with skimmed milk he has always found better than to dilute with water or gruels.

117. **Prophylaxis of Infectious Diseases at Buenos Aires.**—In this twenty-eighth instalment of his great work, "Buenos Aires caritativo y previsor," which has been running through twenty-one issues of the *Semana,* Coni tabulates the statistics since 1877 in regard to the death rate from infectious diseases. The total average in the first decade was 33.2; in the decade ending with 1916, it was only 6.6. Improvement is pronounced all along the line. The relative mortality from diphtheria and croup per ten thousand inhabitants has dropped from 91 to 16; of typhoid, from 59 to 23; of measles, from 17 to 10; of scarlet fever, from 8 to 3, and of whooping cough, from 11 to 6. The fact that all our prophylactic measures have weak links is confirmed by the severe epidemic of measles in 1915, with the unprecedentetd mortality of 358 deaths, far more than in any of the four previous decades. Diphtheria also was responsible for 402 deaths in 1915, nearly twice as many as in any year since 1886. Yellow fever, cholera and smallpox have been conquered. Yellow fever in 1871 killed 20,000 in three months out of a population of 80,000. Coni remarks that it is not enough to pass laws in regard to vaccination against smallpox. A personnel must be organized to enforce them. He describes how this has been done so effectually that there was only one death from smallpox in 1914, one in 1915 and none in 1916.

122 *Foundlings' Asylums. E. M. Villapadierna.—p. 146.

122. **Foundlings' Asylums.**—Villapadierna comments on the large and increasing number of these asylums in Spain, and denounces them as bad from nearly every point of view. Instead of fostering the abandoning of children, efforts should be devoted to helping the mothers to keep and bring up their children, and compel the father to bear his share of the burden. The laws should facilitate the investigation of the paternity, as it is unjust for only one of the two parents of an illegitimate child to bear all the burden. He urges the organization of a society for protection of unmarried mothers.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

123 *Fat in the Urine. J. L. A. Peutz.—p. 728.
124 Experiences with Wassermann Reaction as a Guide to Treatment of Syphilis. J. H. Pameijer.—p. 739.
125 *Traumatic Dermoid Cysts. I. J. Van den Helm.—p. 746.
126 *Scarlet Fever in Parturient. B. Veraart.—p. 748.

123. **Fat in the Urine.**—Peutz remarks that appreciable fat in the urine must be regarded as pathologic unless after ingestion of excessive amounts of fats. Brieger was unable to induce alimentary lipuria in numerous tests, and Peutz found no traces even of lipemia after subcutaneous injection of large amounts of finely emulsified fats. Alimentary lipuria is induced more readily in animals, especially in dogs.

The minute quantities of cholesterol and lecithin found in the urine constitute a physiologic lipuria. This seems to be increased in malaria and tuberculosis, and reduced with cirrhosis of the liver, and lipoiduria may be pronounced with chronic nephritis. A large content of fat acids was found in the urine in a case of phosphorus poisoning, and in a patient with hematoporphyrinuria. The distinction between lipuria, lipoiduria and chyluria has not always been sharply drawn by different writers. Chyliform changes may be induced in the urine by products from tumors, suppuration and infectious processes, a pseudochyluria, or there may be lymphuria. The fat particles can be detected by the microscope, and are dissolved by ether, benzol, ligroin and chloroform, but are scarcely soluble in alcohol, and not at all in water. They also spot paper characteristically.

He discusses the possible causes of chyluria: obstruction of lymph vessels from within or without, obstruction from vasomotor influences, or from infectious processes. In the two cases he reports, the attacks of chyluria were always preceded by pain in the kidney region or side. There was rapid loss of flesh, but severe pulmonary tuberculosis in one case contributed to the emaciation. In the other case the man for twenty years had been occasionally under treatment for what was supposed to be tuberculosis of the kidney, but in the intervals his earning capacity was not much impaired. The chyluria in this case developed only at night, after he had been lying bent over, on his side, and it was always preceded by pain in the side. In a similar case reported by Magnus-Levy, the chyluria occurred only during cold weather and on reclining at night. If the man got up in the night and exercised, his urine cleared up to limpid again. Urine containing milk shows milk sugar, while no sugar, or only grape sugar, is found with chyluria. In treatment of chyluria, a course of antisyphilitic measures is often advisable, and always we can seek to improve the general condition and make up in the diet for the waste of albumin and fat in the chyluria. We must do this even although this may intensify the chyluria. It may be possible, also, to give food of such a kind that it is taken up by the blood capillaries in the intestines, instead of the lymphatics. Subcutaneous injection of fat might also be tried, although to date we have no convenient and effectual method for supplying needed calories by subcutaneous injection of fat; olive oil is liable to entail a painful infiltration which disappears only very slowly.

125. **Traumatic Dermoid Cyst.**—Van den Helm applies this term to tumors developing from implantation of particles of skin into deeper tissues, either during an accident or in some operation. The mechanism is thus the same in the acquired, traumatic form as in the congenital. In both his cases the "implantation cyst" developed several years after a radical mastoid operation. The growth was removed under the diagnosis of atheroma; it was adherent to the scar tissue and to the deeper tissue below.

126. **Scarlet Fever and Umbilical Infection.**—The child died the second day after an extremely rapid spontaneous birth, the discolored umbilical cord explaining the fatality. The mother developed septic fever and died ten days after delivery. No cause for these tragic occurrences could be discovered until an eruption of scarlet fever on one of the other children in the family, just before the death of the mother, explained the sepsis.

128 Roentgen Findings in Fractured Calcaneum during Life and After Death. T. Eiken.—p. 365.
129 Present Status of Benign Glycosuria. E. Jarløv.—p. 370.

127. **Surgery of Vessels.**—In the first of Ipsen's three cases, he resected a femoral arteriovenous aneurysm and implanted a section of the femoral vein, with excellent results. The lesion had developed after a pistol wound in the region. In two other cases he opened the popliteal artery to extract an embolus. The first patient was a young woman who for years had presented symptoms of heart insufficiency and finally of embolism in the popliteal artery. There was pronounced necrosis of tissues when the case was first seen, nine days after the embolism. Amputation seemed inevitable, but the leg turned reddish as the embolus was removed and under careful management the leg was saved. Although the embolus was of eleven days' standing, it had not become adherent to the vessel. The case teaches that much can be ventured even in old cases. In the second case there was thrombosis elsewhere, responsible for the fatal outcome a few days later.

133 Invagination by Meckel Diverticulum. A. Vangsted.—p. 480.
134 *The Death Rate and Causes at Copenhagen 1715. P. Heiberg. —p. 486.

130. **Falling of the Hair an Early Sign of Syphilitic Meningitis.**—Pedersen remarks that the modern diagnosis of syphilis is a "matter of punctures," but that puncture to obtain spinal fluid can sometimes be dispensed with as the behavior of the hair reveals pathologic conditions below. Cyranka and Gärtner have reported that the spinal fluid was found notably pathologic in all but two of thirty-five soldiers with alopecia leukodermica. Nineteen of the men had never been treated for their syphilis, which dated from two months to two years, while the others had been given more or less treatment. It was noted further that the Herxheimer reaction was unusually pronounced in men with patches of thinning of the hair, and that exceptionally vigorous specific treatment was required before it subsided. In three other cases (optic neuritis, general paresis and incipient tabes), with an interval of from two to six years since the infection, each had had patches of alopecia early in the disease. This indicates that the virus had attacked the meninges early. Pedersen reports a group of ten cases in which different manifestations of syphilis—acquired, in all probability, less than five months before—were accompanied by a general falling of the hair. This sign of injury of the meninges was observed before the spinal fluid presented pathologic findings, with two exceptions. In another group of ten patients the falling of the hair occurred in irregular patches, along with other manifestations of syphilis. The infection dated mostly from six to nine months; in none from less than three months. The spinal fluid findings were positive in all but two who had been given extra energetic treatment. Pedersen concludes from these experiences that syphilitic meningitis occurs more frequently along with irregular patches of thinning or falling of the hair than with any of the other clinical manifestations of syphilis. Hence syphilitics showing even a suggestion of a "mangy" appearance of the scalp should be given particularly vigorous treatment, and be kept under close and prolonged supervision, and the spinal fluid should be examined at the close of the first year of treatment, unless symptoms on the part of the central nervous system call for this earlier.

134. **The Causes of Death at Copenhagen in 1715.**—An official report with this title and the date has recently been found among the state papers of Denmark. Nearly fifty different causes of death are listed for the total 2,265 deaths during the year, to a population of about 50,000. The list includes 58 stillborn and 141 newborn children, and 239 deaths from diseases of the chest; 82 from consumption; 632 from smallpox; 364 from "stroke" (convulsions) mostly in children; 189 general debility; 21 from dropsy; 2 from epilepsy; 72 from "fever"; 85 from "violent fever", and 108 from old age. Only 7 deaths from violence are recorded, and 5 from accidents during the year. One fatal case each of periodical insanity, melancholia, and hernia is reported; 9 persons were executed, and the death of 30 is ascribed to scurvy. Four years before the date of this report was the great plague year, which reduced the population from 66,000 to 44,000.

THE WAR SERVICE OF THE MEDICAL PROFESSION

A SURVEY INCLUDING THE NAMES OF CIVILIAN PHYSICIANS IN MILITARY SERVICE AND A TABULATION OF STATISTICS BY COUNTIES AND STATES

The same principle that requires each state or community to furnish its quota of men for the Army should also apply in securing physicians for the Medical Reserve Corps. To determine to what extent the various parts of the country had met this responsibility, the American Medical Association last winter compiled a list, by states and counties, of the physicians who had accepted commissions in the Medical Reserve Corps. This first survey was completed in March, and the matter down to and including Maryland was published in the American Medical Association *Bulletin.* It was the intention to publish the rest of this survey in the next issue of the *Bulletin* without delay. However, as the preliminary survey included only physicians who had accepted their commissions up to January, 1918, and therefore was not up to date, the War Committee of the American Medical Association directed that this preliminary survey be revised and completed to date of publication so far as possible. The War Committee, believing that all physicians should have this information, decided to publish it in THE JOURNAL, rather than in the *Bulletin,* the regular circulation of which is limited to the presidents and secretaries of the component county and constituent state associations.

Another reason for this action by the War Committee was the receipt of Surgeon-General Gorgas' letter[1] of April 3, requesting the cooperation of the American Medical Association. The Surgeon-General stated: "The additional increase in the Army during the next few months will probably necessitate the service of 5,000 physicians who as yet have not made application for a commission in the Medical Reserve Corps . . . it is estimated that the Medical Reserve Corps will need a steady increase of at least 2,500 applicants a year during the continuance of the war." Paragraphs five and six of his letter read:

> "5. It is earnestly desired that the interests of the civil communities be conserved as far as possible and that no enlistments in the Medical Reserve Corps be made that would work serious hardship upon any community, manufacturing concern or other civil activity by taking from such community, manufacturing concern or other civil activity, physicians whose services are needed for the efficient and competent care of the civil population or the employees of large concerns.
>
> "6. To this end the department desires the closest cooperation and assistance of the American Medical Association, its officers and its allied organizations, believing that through its organizations the additional [illegible]ment to the Medical Reserve Corps can be most satisfactorily obtained and the necessary increment for [illegible]nts be secured without in any way depriving any community of physicians whose services are necessary [illegible]welfare and without depriving any manufacturing or other concern of its medical personnel when [illegible] cannot be spared."

Th[illegible]ble that physicians should be familiar with the information contained in the survey in [illegible]ay better help in carrying out effectively the sentiments expressed in paragraphs five [illegible]rgeon-General's letter. All the data concerning each state are assembled in a table accom[illegible]ter for the state. These tables make it possible at a glance to determine the important facts [illegible] county: the area, population, total number of physicians, number of physicians under 45 and [illegible]rs of age, number of women physicians, total number of physicians in the county, number of [illegible] the county society, and the number and names of physicians who are already under commission [illegible]y or in the Navy. The last column of the table is the most important one. It lists the number [illegible]ns in the federalized National Guard, as well as commissioned medical officers in the Reserve [illegible] the Army and the Navy. It does not include the regular Medical Corps of either the Army or [illegible]; those who have been commissioned but have not yet accepted their commissions; or those who

are serving as contract surgeons. It must be borne in mind, therefore, that this last column of the table does not include those who have made application for commission, or even those who have been awarded a commission unless that commission has been accepted. At the present writing, May 24, there are many pending applications.

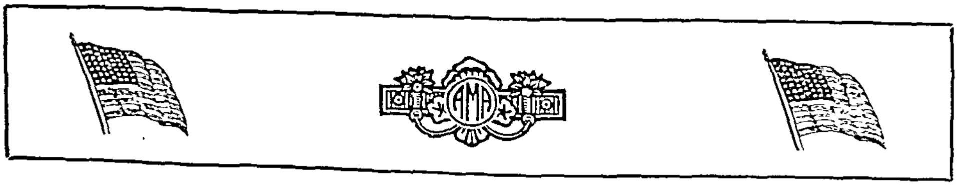
The preparation of this survey has been a difficult undertaking. Undoubtedly the data are not perfect: some names may have been included that should not have been; more likely, some have been omitted that should have been included. We ask our readers, and especially county secretaries, to check over the Honor Roll and the tabular data covering their particular county, and to send corrections or comments to Dr. A. R. Craig, Secretary of the American Medical Association, 535 N. Dearborn Street. It is urged that this be done promptly, so that a corrected and amplified survey may then be made available to the component societies of every state. This survey for component societies will be in the form of a list of registered physicians for the territory covered; on it will be indicated not only those physicians who have accepted commissions, but also those who have made application for commission, those to whom commissions have been granted but who have not yet accepted them, etc. Those coming within the age limits for the Medical Corps and the Medical Reserve Corps of both the Army and Navy will also be indicated.

In addition to the table in each state, a similar table will be found at the end of the survey covering the whole country. This latter table, besides assembling the totals for each state, shows the percentage of the medical profession already commissioned in each state.

We may estimate that in addition to the Regular Corps, a total of 30,000 medical officers will be required for the present year—27,500 for the Army, and 2,500 for the Navy. The number of physicians in the United States, according to the new American Medical Directory now on the press, is 146,500. Hence it will take between 20 and 21 per cent. of the total number of physicians of the country to supply the 30,000. This means as a minimum one in five. To supply one out of every five physicians to the Government, if managed rightly, ought not to be a severe strain on our profession. There are many communities and industrial centers that can not spare any physician; on the other hand, there are many that can easily spare two out of five. This is especially true of large cities.

Finally, the purpose of this survey is to make available to physicians in every community of the country information which may assist them in determining whether or not their locality is meeting its obligation in providing the needed number of physicians for military duty. The county societies naturally are best qualified to pass on the actual needs of the civilian population of their territory, as well as to furnish information relative to the personnel of the profession. For evident reasons the county society may not always be able to decide who should and who should not volunteer. Such problems can sometimes be better worked out through the cooperation of the county society with the War Committee of the state association and of the American Medical Association. With the state and county organizations cooperating, there is little doubt that each state will be able to supply its quota without serious hardship on either the civilian population or individual members of our profession.

NOTE.—Many names were added after the Honor Roll was in page form. These are inserted under the respective counties but out of alphabetical arrangement. *They are in italics.*—ED.



MEDICAL ASSOCIATION OF THE STATE OF ALABAMA

Officers 1918-19

I. L. Watkins, President..............Montgomery

1. Includes Little Rock, population 55,158; physicians 186 [M.R.C. 44].

Crittenden County

EARL—Samuel McAlister Mauney; Herbert Shirley Watson. PROCTOR Thomas Wilson. SEYPPEL—Henry Pender Ledford. TURRELL—Floyd Webb.

Desha County

DUMAS—Alphonso Isom; Wm. Golladay O'Neal. McGEHEE—R. Newman Brown.

Drew County

MONTICELLO—James Milton Best; Edward Ralph Cotham; Mardello Yates Pope. PLANTERSVILLE—John Samuel Wilson.

Franklin County

BRANCH—Wm. J. King.

Fulton County

MAMMOTH SPRINGS—Arch Sylvester Chapman.

Garland County

HOT SPRINGS—John William Rush; John Graydon Cullins; Maurice Farrish Lautman; William Kate Smith; Frederic Earl Diemer; Allen C. Prichard; Harry Morris Strachan; Grayson Emery Tarkington; Loyd Thompson; Henry King Wade.

Greene County

PARAGOULD—Erasmus S. Baker; Frank Lawrence Castleberry.

Hempstead County

HOPE—Victor K. Allen; Robert Ellis Weaver.

Hot Springs County

DONALDSON—Morgan C Berry.

Independent County

BATESVILLE—Charles Garland Hinkle.

Jackson County

TUCKERMAN—Oscar Aden Jamison.

Jefferson County

HUMPHREY—Thomas Dobbins. PINE BLUFF—John Short Jenkins; J. F. Lieberman; William Thomas Lowe; J. William Scales; Loren Wallin.

Lafayette County

LEWISVILLE—Joseph R. Smith. STAMPS—Carland A. Ellis.

Lawrence County

RICHWOODS—Wm. Henry White. WALNUT RIDGE—George Maxey Watkins.

Lee County

HAYNES—William Robert Haynie. MARIANNA—Mac McLendon.

Lincoln County

VARNER—Anthony Claudius Thiolliere.

Little River County

WILTON—Arley Doyne Cathey.

Logan County

BOONEVILLE—Forrest P Baker; Austin R. Hederick. DRIGGS—Felton William Laudrum. SCRANTON—Arless A. Blair; Everett Newton Lipe

Lonoke County

CABOT—Paschal Josephus Park. ENGLAND—Cap. J. Carter.

Marion County

RUSH—Sherod A. Drennen.

Miller County

TEXARKANA—Theron Earle Fuller; William Hibbetts; Perry Crittenden Williams; Edwin Berry Buchanan.

Mississippi County

BARFIELD—Cinc'nnatus Hine Miller Mason; Wheeler Scott McCall. BASSETT—Oscar Barksdale. BLYTHEVILLE—Wm. *Thomas Polk*; Max Overton Usrey. CLEARWATER—Amos Elmer Robinson. OSCEOLA—Wilbur Russell Harwell, William Joplin Sheddan.

Monroe County

CLARENDON—Matt Francis Huston; Philip Emerson Thomas Jr. HOLLY GROVE—Paul Edward Johnson.

Ouachita County

CAMDEN—Braxton Victor Powell.

Perry County

APLIN—Ervin L. Matthews. CASA—Hugh C. Brooks.

Phillips County

HELENA—James William Butts; Aris Joseph Samuel Davidson; Wellington Cox MARVELL—Robert *Cain* Meadors; George Edward Penn. WABASH—George Washington Eubanks. WEST HELENA—Henry Watkins Allen Lee.

Poinsett County

LEPANTO—Chas. Elbert Byler.

Polk County

MENA—Elmer Ellsworth Holt.

Pope County

ATKINS—Arthur Ceberry Haney. RUSSELLVILLE—James Fred Hays.

Prairie County

LOOKOUT—Garfield B. Morre.

Pulaski County

[illegible] w; *Lincoln Humphreys*; William Elvage Mc-
L[illegible] [illegible]OTS—John M. Hewitt.
P. [illegible] Franklin Ball; Edwin Page Bledsoe; Sterling [illegible] Gardiner.
[illegible] Allaire Dashiell; Edward Owens Day; Robert Manley Eubanks.

Wayne Neal Freemyer; Dewell Gann Jr.; Davis Wolf Goldstein.

Alfred Gilliam Hearn; Hugh B. Henry; Sherman Booker Hickman; Homer A. Higgins; Shelbey Boone Hinkle; Glen McK. Holmes.

Alvin Leondus Jobe; Roscoe Conklin Kory; Dee C. Lee.

Guy Arnold McCormack; Martin P. McNeil; Clinton P. Meriwether; Arthur Lee Mobley; Henry E. Mobley; Robert B. Moore; Nolie Mumey; Patrick Murphey; Mahlon Dickerson Ogden.

Lee Vallette Parmley; Feaster LeGrand Proctor; Ernest Whitfield Prothro.

Nicholas William Riegler; Wallace Dickinson Rose; Scott Clark Runnels.

Rector Philip Sheets; William Anderson Snodgrass; Alvin Weil Strauss.

Francis Vinsonhaler; Perry V. Wagley; Fay Powell Washington; Asa C. Watson; James R. Wayne; Raymond Clyde Wolfe; Geyer Chauncey Wood.

SCOTT—John Bridger Wells.

Randolph County

O'KEAN—Marshall Allen.

Saline County

BAUXITE—Robert H. Bryant; Homer Scott. BENTON—Sidney R. Crawford. HASKELL—Boulanger Gwaltney.

Searcy County

MARSHALL—Isaac Striman Butler.

Sebastian County

BONANZA—Rufus Francis Parks. FORT SMITH—Carl Sperry Bungardt; Walter G. Eberle; Miles Everett Foster; Arthur Franklin Hoge; Constant P. Wilson Jr. HARTFORD—George McKellar; Horace Porter Routh. MANSFIELD—John Royston Brown.

Sevier County

LOCKESBURG—James Fleming Musser.

St. Francis County

COLT—Newman Burgess Burch. FOREST CITY—David Oliver Bridgeforth. HUGHES—Edward Wesley Pollard. WIDENER—Woodbye Albert Winter; Ernest Darnall.

Union County

HUTTIG—Foster Jarrell. WESSON—James Wiley Slaughter.

Van Buren County

CLINTON—Robt. Marvin Hunter. SHIRLEY—James Fletcher Poe.

Washington County

ELM SPRINGS—Horace William Graves. EVANSVILLE—Bert Cecil Hiner. FAYETTEVILLE—Donald Ray Wilson. SPRINGDALE—Otto Christian WINSLOW—Thos. Ellsberry Gray.

White County

BEEBE—W H Abington; Bernie F. Jungkind. EL PASO—W. H. Bruce. JUDSONIA—Wylie Robert Felts. SEARCY—Samuel T. Tapscott Jr. WEST POINT—James Madison Wellborn.

Woodruff County

GREGORY—Frank Carroll Maguire.

MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

Officers 1918-19

Cornelius Van Zwaluwenburg, President........................Riverside
John H. Graves, First Vice President.....................San Francisco
Ferdinand Stabel, Second Vice President.........................Redding
Saxton T. Pope, Secretary................Butler Bldg., San Francisco

Councilor Districts and Officers

C. G Kenyon, Chairman, San Francisco.

Councilors at Large.—H. A. L. Ryfkogel, San Francisco; O. D. Hamlin, Oakland; Rene Bine, San Francisco; Geo. H. Kress, Los Angeles; J. C. Yates, San Diego; G G. Moseley, Redlands.

First District—San Diego, Riverside, Orange and San Bernardino counties. C. Van Zwaluwenburg, Councilor, Riverside.

Second District.—Los Angeles, Ventura, Santa Barbara and Kern counties. E C Moore, Councilor, Los Angeles.

Third District.—San Luis Obispo and Monterey counties. T. C. Edwards, Councilor, Salinas.

Fourth District.—Fresno, Kings, Tuolumne, Merced, Mariposa, Madera and Stanislaus counties. Geo. H. Aiken, Councilor, Fresno.

Fifth District.—Santa Clara, San Mateo, San Benito and Santa Cruz counties. P. T. Phillips, Councilor, Santa Cruz.

Sixth District.—San Francisco County. C. G. Kenyon, Councilor, San Francisco.

Seventh District.—Alameda, Contra Costa, San Joaquin and Calaveras counties. E. N. Ewer. Councilor, Oakland.

Eighth District.—Alpine, Amador, Butte, Colusa, El Dorado, Glenn, Inyo, Lassen, Modoc, Mono, Nevada, Placer, Plumas, Sacramento, Shasta, Sierra, Siskiyou, Sutter, Tehema, Yolo and Yuba counties. Jas. H. Parkinson Councilor, Sacramento.

Ninth District.—Del Norte, Humboldt, Lake, Marin, Mendocino, Napa, Sonoma, Solano and Trinity counties. A. W. Hoisholt, Councilor, Napa.

HONOR ROLL

Alameda County

ALAMEDA—Wilfred F. Beerman; James Kish Hamilton Jr.; William Tappen Lum, Leland O. W. Moore; Herbert Piercey Nottage.

BEREKELEY—Warren Barrett Allen; Edward Cline Bull; John W. Callnon, Harvey Philip Charles; Mendel Cohn; James Gordon Cumming; Samuel Robert Downing; Henry Stone Forbes; Harry Emerson Foster; Fredk Parker Gay; Harry Newton Kierulff; Robert Thomas Legge; Arthur Merrill McIntosh; Albert Mauson Meads; Ernest Howard Pape; Wibur Augustus Sawyer; Walter Reese Scroggs; Richard Watts Soper; Herbert Sedgefield Thomson.

HAYWARD—Charles John Harbeck. LIVERMORE—Paul Egan Dolan; Clifford W. Mack.

HAYWARD—Howard Charles Crum.

OAKLAND—John Peter Byrnes; Wilfred E. Chambers; Cornelius Thomas Devine; William Lawrence Dunn; Henry M. Fine; Louis Alliston Frary; Channing Hall; Gordon Batteile Hamilton; *John Theodore Kergan*; Alva Frank Maine; Herbert Arthur Makinson; Donald Murdock McRae; William Patton Milliken; Vaclav Horace Podstata; Alvin Powell; John Morse Rehfisch; Bruno Francis Sandow; Melvin Arthur Shade; Don D. Weaver.

SAN LEANDRO—Gail Fehrenson; Wm. R. Leahy; William C. Lynch; Clarence Alfred Wills.

Amador County

IONE—George Giles Hawkins.

Butte County

GRIDLEY—Elmer Ellsworth Martin. OROVILLE—Frank Moore Whiting.

Alpine county has no physicians within its territory and is not listed in this table.

1. Includes Berkeley, population 54,879; physicians 119 [M.R.C. 17], and Oakland, population 190.803; physicians 325 [M.R.C. 19].
2. Includes Los Angeles, population 475,367; physicians 1.333 [M.R.C. 165], and Pasadena, population 43,859; physicians 130 [M.R.C. 15].
3. Includes Sacramento, population 64.806; physicians 108 [M.R.C. 13].
4. Includes San Diego, population 51,115; physicians 190 [M.R.C. 33].
5. Includes San Francisco, population 448,502; physicians 1,239 [M.R.C. 210].
6. Includes Stockton, population 34,508; physicians 65 [M.R.C. 5].
7. Yosemite National Park.

Humboldt County

EUREKA—Thomas Robert Petch; Carl Wallace. FERNDALE—Francis Marion Bruner; Greg Hoskins.

Imperial County

CALEXICO—George Newlove; Walter Leon Elis. EL CENTRO—Charles Stanford Brooks.

Inyo County

BIG PINE—John Royal Buckingham. LONE PINE—Mark Angle Williamson.

Kern County

BAKERSFIELD—George Marion Bumgarner; Clarence William Kellogg; Malcolm Yeaman Marshall; Liva Charles McLain; Homer Rogers; Joseph Kent Smith. McFARLAND—John Nelson Blood.

McKITTRICK—Samuel Bryan Degman; Julius R. Hamilton.

Kings County

HANFORD—Budd Robbins.

Lake County

BARTLETT SPRINGS—Reuben H. Hunt.

LAKEPORT—Ernest Clarence Griner.

Lassen County

MADELINE—Lynn Carl Smith.

Los Angeles County

ARTESIA—Edward Henry Diehl. BURBANK—Harry X. Cline. COVINA—Wallace Allison Reed. CULVER CITY—Robert Maxwell Jones; Bryant Robert Simpson. DOWNEY—David Burdette Zbinden. EL MONTE—Joseph Saylin. GARDENIA—Francis Belmont Dwire. GLENDALE—John Warren Bardill. GLENDORA—Harrie Chamberlin. HAWTHORNE—Allan Napier Kerr. INGLEWOOD—Louis Nels Anderson. LA MANDA PARK—Owen Melville Harrah. LANKERSHIM—Elliott Plummer Smart.

LONG BEACH—Robert Metcalf Dodsworth; Harry H. Heylmun; Leo De Scott; Charles Henry Miller; Roderick Hoffman Shippey; George Tupper.

LOS ANGELES—Charles Blackstone Adams; Eliot Alden; Albert Allen; Carlton Stewart Allen; Samuel Mitchell Alter; Francis Xavier Ammann Jr.

LeRoy Harrison Bailey; Claudius Ballard; Fred J. Barnet; Winfield Lincoln Bartow; Samuel G. Bay; Wendell P. Blake; William Otis Blanchard; Phil Boller; Karl Marx Bonoff; Frederick A. Bonthuis; Fred Phelps Bowen; William B. Bowman; John Ira Boyer; Walter Vernon Brem; Hersel Eugene Butka; Lawrence J. Butka; Oliver William Butler; Ralph L. Byrnes.

John Carling; Ray Alden Carter; William James Chambers; Albert Charlton; Guy Cochran; Frederick Amasa Coler; Clare Pattee Conroy; James R. Cowan; Edward Rockford Cox; Egerton L. Crispin; Philip John Cunnane; Thomas B. Cunnane.

William Hardy Daniel; Bertram Charles Davies; Charles W. Decker; Frank Raymor de la Vergne; Karl Lyonel Dieterle; Robert Black Dimon; Clarence Wythe Dodge; Wallace Dodge; Normand F. Dorn.

Joseph Gamewell Evans; John Eugene Fahy; Fred Durfee Fairchild; D. C. Farnsworth; Abraham Feldman; John C. Ferbert; James Tucker Fisher; William Vare Chalmers Francis; David Fredericks; Chas. E. Freedman; Donald J. Frick; Lowell Chester Frost; Dudley Fulton.

Hiram Gallagher; Charles Louis Garvin; Albert Carl Germann; James Peter Gillis; Albert Sidney Gough; *William Lewis Grant.*

Robert Kels Hackett; Ralph Hagen; James Sprunt Hall; George Louis Alexis Hamilton; Roy Wallace Hammack; Lasher Hart; Truston Mitchell Hart; Miles Aiken Heffelfinger; James Walter Heustis; Robert Burns Hill; Walter Martin Holleran; Foster Miller Hull; Daniel Louis Humfreville; George Graham Hunter.

Clarence Edward Ide; John Curtis Irwin; Nilton D. W. Jeffs; Simon Henry Jesburg; Louis Josephs; Guy Leslie Kay; Walter P. Keene; Henry Sheridan Keyes; Walter Christian S. Koebig; Harry Haynes Koons.

Walter Eber Leonard; Fred Ellsworth Lettice; L. R. Linhart; Lorenzo Foster Luckie; Earl Lane Lupton; Jerre G. Lynch.

Lloyd Russell Mace; Chester Lea Magee; Harry George Marxmiller; Norman M. McClelland; Clark Loring McClish; Wm. Raymond McDannell; James Henry McLaughlin; Thomas R. McNab; Frank W. Miller; James Lewis Miller Jr.; Egbert Earl Moody; Edward Clarence Moore; J. Ross Moore; Wayland Augustus Morrison; Lewis B. Morton.

William H. Olds.

Paul Alfred Opp; Thomas Janes Orbison; Thomas William O'Reilly.

Arch Marty Paulson; Arthur Lewis Peter; Giles Scammon Porter; Russell Warren Prince; Carl Wheeler Rand; Fred Sylvester Ray; George William Reyer; William W. Richardson; Edwin Jules Riche; Paul Brandt Roen; Roy Frederick Ruth.

Arnold E. Saverein; George Frederick Schenck; Arnold Max Scholz; Joseph L. Schwartz; Paul Kibbe Sellow; John Russell Shea; Bernard Shelton; Leon Shulman; Fred Cazeoux Shurtleff; Rea Smith; Albert Soiland; James Steinberg; Charles Gaskill Stivers; Byron Polk Stookey; Leonard Stovall; John Swancott; Bret Albert Swartz; Percy Edward Swift.

Robert L. Tebbett; Emil Francis Tholen; Frank Thomas; James Thornton; Delos Packard Thurber; Frank M. Trout; Kenneth Beymer Turner; Arthur Maurice Tweedie.

Jean J. A. Van Kaathoven; Harry Voorhees; George Phillips Waller Jr.; Frederick Beall West; Sydney Vatelle West; Charles Green Wharton; Sandford Blanding Whiting; James Thomas Whittaker; Edwin Hardin Wiley; Clair Wilson; John Cree Wilson; Charles Stephen Young.

LOS ANGELES—Charles Frederick Curtis; William Allan Swim; Stephen Yerkes Van Meter; Asa George Woodward.

MONROVIA—Francis M. Pottenger; Lewis Durkee Remington. NORWALK—Preston Stanley Kellogg; Charles E. Sisson. OCEAN PARK—Oscar Anderson.

PASADENA—John H. Breyer; Joseph Dayton Condit; Frank Moore Connor; Henry Ambrose Hoit; Robt. K. Macklen; Fitch C. E. Mattison; Samuel Jones Mattison; Alva Dutton Stearns McCoy; Edwin Harbaugh McMillan; James Ross Reed; Levi Lore Riggin; William Humes Roberts; Henry Howard Sherk; Robert L. I. Smith; Edward Everett Tredway. PATTON—Emil William Meyer.

POMONA—Dumont Dwire; Homer Carlton Seaver. SAN GABRIEL—Oto David Chamley. SAN PEDRO—Reuben H. Hunt; Wm. Day Moore. SANTA MONICA—John A. Balsley; Hugh King Berkley. SAWTELLE—August Benjamin Hromadka; George Anderson Fielding. SOLDIERS' HOME—Kay Walter Karras. SOUTH PASADENA—Russell Ross Burt; Fred Detmar Northup. VENICE—Arthur Cooper Smiley. WHITTIER—Horace Plummer Wilson.

ALHAMBRA—James Archibald Keown.
SOLDIERS HOME—Walter D. Bishop.

Marin County

FORT McDOWELL—Eugene L'Hommedieu Swift, Richard Carl Dienst. MILL VALLEY—Oscar Park Stowe; Lemuel Alfred Anthony. SAN QUENTIN—John Edwin Paulson. SAN RAFAEL—Rafael Gabriel Duffley; James Stone Waid. SAUSELITO—Allen H. Vance.

Mendocino County

ALBION—Homer Holsinger Wolfe. WILLITS—Raymond Arthur Babcock.

Merced County

LOS BANOS—Fred F. Sprague. MERCED—Edwin Ray Fountain; Daniel Webster Zirker.

Modoc County

ALTURAS—Walter Edwin Coppedge; Alexander Gibson. *EAGLEVILLE—Milo Russell Kennedy.*

Monterey County

PACIFIC GROVE—Frank Russell Hart. SALIVAS—William Rollin Reeves.

Napa County

CALISTOGA—Cyril Ettrick Lewis. OAKVILLE—Samuel Chester Leonhardt.

Nevada County

GRASS VALLEY—Paul D. Barnes.

Orange County

FULLERTON—William Harold Wickett. GARDEN GROVE—Oscar Ollie Young. HUTINGTON BEACH—John Edwin McKillop. ORANGE—Willis Henry Hall; Martin Passmore Hamrick. SANTA ANA—Frank E. Winter.

Placer County

ALTA—Robert Carnahan Kirkwood. COLFAX—Henry Thomas Rooney. LINCOLN—Orra Crosby Hyde; Frank Edward McCullough.

Plumas County

PORTOLA—Samuel McCoy Sproat.

Riverside County

BLYTHE—Frank Alexander Lowe. CORONADO—Robert Smart. RIVERSIDE—Bon O'Driscol Adams; Arthur Leon Brown; Wendell A. Jones; George Carl H. McPheeters; William Wallace Roblee; William Donald Rolph; George Hamilton Trevelyan; Clark Denike Fanton.

Sacramento County

FOLSOM—Myer Jacob Wahraftig. SACRAMENTO—Clarence Lavan Bittner; Howard McDougall Cameron; Joseph William Crawford; A. B. Diepenbrock; Nathan George Hale; Marion Reginald King; Edward S. Loizeaux; Arthur Lee Munger Jr.; Orris Reid Myers; James H. Parkinson; James Roe Snyder; Warren Willis Strange; Eldridge C. Turner. WALNUT GROVE—Ernest Everett Wilson.

San Bernardino County

LOMA LINDA—Alton De Forest Butterfield; Charles William Harrison; Fred E. Herzer. NEEDLES—Arthur Edward Boland. ONTARIO—Charles Andrew Warmer PATTON—Emil William Meyer; Victor Parkin. REDLANDS—Charles Edward Ide. SAN BERNARDINO—Louis Milton Coy; Thomas Richard McHugh; John Herman Meyer; Henry William Mills; Ralph Merle Smith; Colin Campbell Owen; Gilbert Roy Owen TRONA—Homer Richard Evans. UPLAND—John B. Craig.

San Diego County

FALLBROOK—John C. Graffin.

LEMON COVE—Morton William Fraser; Robert Bruce Montgomery. LINDA VISTA—John Peachay Jones.

SAN DIEGO—Alfred Edward Banks; Arthur N. Bobbitt; Alfred Byars; Ross S. Carter; James F. Churchill; Vernon G. Clark; Gordan Courtenay; Francis Jordan Dingeman; Joseph Foster Grant; Maynard Caldwell Harding; Gilbert Franklin Harris; Arthur John Holeton; Rutherford Buchard Irones; Robert S. Irvine; James Albert Jackson; Lyell C. Kinney; Thomas C. Little; Harry Clifford Loos; Allyn Claude Magee; Thomas B. McCowan; Frederick W. Muller; Bernard O'Neill; Joseph Andrew Parks; Thomas C. Pounds; William R. Ream; Frederick J. Smith; Frank W. H. Taylor; Robert W. Thomas; Paul Wegeforth; Andrew Benj. Wessels; Thomas F. Wier; Arthur John Wilkinson; George Barrow Worthington.

TECATE—Edward H. Jordan.

San Francisco County

ALCATRAZ—Herbert William Yemans. FORT MILEY—Justus M. Wheate. SAN FRANCISCO—Le Roy Chas. Abbott; Henry Abrahm; Bertram F. Alden; Frederick Emerson Allen; Ewald H. Angermann; Frank Ashmore.

Walter Isaac Baldwin; Nathan Powell Barbour; Hans Barkan; George D. Barnett; Shadworth O. Beasley; Joseph L. Bell; Gustav Julius Bergener; Elbridge John Best; William Archdall Boyle; Frank Philip Brendel; Frank J. Breslin; Joseph Richard Brown; Frederick Bryant; William A. Bryant; Sterling Bunnell; Edmund W. Butler.

Rawlins Cadwallader; Erwin Julian Casper; Donald Cass; Paul Castelhun; Joseph Henry Catton; William Chamberlain; John F. Chapman; Ernest Dwight Chipman; William Redwood; Price Clark; Ernest Winton Cleary; Herbert Jacob Cohn; Orrin Simeon Cook; Chas. Alfred Craig; Lloyd Benjamin Crow; Charles Cross.

Arthur Lee Davis; William B. Deas; John Paul Degnan; Victor d'Ercole; Richard L. Dowdall; Hiram B. Duncan; George Michael Dunne.

Earl Eames; Leo Eloesser; Leonard Wheeler Ely; Frank S. Emmal; Michael Henri Etcheverry.

Harold Ernest Faber; Ernest Henry Falconer; Walter Wallace Fenton; Bruce Ffoulkes; Roy L. Fielder; Arthur Lawrence Fisher; Thos J. Flynn; Cuthbert Merwin Fleissner; Howard Webster Fleming; Harold Augustus Fletcher; Paul J. Flory; Meyer Bernard Fractman; Marius Andre Francoz; *Jule B. Frankenheimer*; John Percival Frizell.

Frederick Mears Gedney; Clain Fanning Gelston; Edward Joseph Ghidalla; Morton Raymond Gibbons; Arthur C. Gibson; Frank Robert Girard; Cosmos Andrew Glover; Arthur Goettsch; Louis Jean Ernest Gouguet; Jonathan Green; Earl Norman Greenwood; Charles Francis Griffin.

Sylvan Lewis Haas; John George Harrington; Chester S. Harris; Ernest Downing Hatch; Harrison Morton Hawkins; George Kramer Herzog; Albion W. Hewlett; Harold P. Hill; Frank Munson Hillyer; Obe Haight Hoag; Herman Verplanck Hoffman; Laurence Harold Hoffman; Thomas G. Holmes; Henry Wells Horn; Louis Phillippe Howe; Robert Cravens Howe; Walter A. Howell; George Rucian Hubbell; Thomas Eugene Hunt; Thomas W. Huntington; Robert Koehler Hutchings.

Thomas G. Inman; William John Jackson; Emil O. Jellinck; Smith Steinberger Johnson; Walter S. Johnson.

Joseph James Kavanagh; William Elwin Kay Jr.; William John Kerr; Eugene Sterling Kilgore; Lester Kimberlin; Frederick W. Kroll; Boyd M. Krout; Harry P. Krummes.

Harry L. Langenecker; Charles Nelson Leach; Claude Clay Leaverton; Cory Childs Ledyard; T. B. W. Leland; Charles Gabriel Levison; Frederick Clinton Lewitt; Melville Hammond Long; Thomas Sherman Long.

George Jewett McChesney; Horace Hoagland McCoy; Albert B. McKee; Arthur Clinton McKenney; Raymond B. McNamara; Albert H. McNulty; Hiram Edghr Miller; A. J. Minaker; Harry S. Moore; William Leander Moore; Charles Espey Mordoff; Norman D. Morgan; Joseph Mora Moss; Vinton A. Muller; William Everett Musgrave; Stanley L. Myre.

Howard Christian Naffziger; Robert Reid Newell; Alfred James Norman; Archibald Angus Norton; Earl William O'Donnell; Harry R. Oliver.

Rey Harvey Parkinson; Charles Arthur Pauson; Robert Allen Powers; Lionel David Prince; Harry Jerome Pruett; George William Purcell; Clarence Quinan.

Jay Marion Read; Frank Birckhead Reardan; Alfred C. Reed; Arthur Henry Reinstein; John Jacob Richstein; Emmet Rixford; John Wirt Robinson; Thomas Bryan Roche; Joseph Henri Denis Roger; Louis David Roncovieri; Howard Edwin Ruggles; Russell Colquhoun Ryan.

William Ashford Sampson; Walter F. Schaller; Herman J. Schlageter; Charles E. Schwartz; Martin Joachim Seid; Leon Gross Seidenfeld; Clyde Everett Shedd; Harry Mitchell Sherman; George Franklin Shiels; John Wilson Shiels; John Jacob Smith; John Bostwick Spalding; Otis B Spalding; Henry Augustus Stephenson; William E. Stevens; Stanley Stillman; John Philip Strickler; Harrison W. Stuckey; Robert Porch Sturr.

Pleasant Addition Taylor; Wallace Irving Terry; Philip M. Thomas; Wm. Benbow Thompson; Tilton Edwin Tillman; George Perkins Tolman; Frank Pixley Topping; Carles Lee Tranter; Ronald B. Tupper.

Benjamin H. Vian; Gabriel J. J. Vischi; Albert B. Vogel; Henry Lewis Wagner; Calvin Albert Walker; Julian L. Waller; William Wallace Washburn; Alanson Weeks; Emmett LeRoy Wemple Jr.; Jas L. Whitney; Glover B. Wilcox; Harry D. Williams; Robert B. Williams; Walter H. Winterberg; Julien M. Wolfsohn; John Homer Woolsey; Harold Walgrove Wright; Harold Zimmerman; Elmo Russell Zumwalt.

SAN FRANCISCO—Mervyn Heller Hirschfeld; Ray Wright Rosson; Harry Travis Summersgill; James A. Young.

SAN LEANDRO—William H. Leahy.

San Joaquin County

SAN JOAQUIN—Lester E. Tretheway. STOCKTON—Ambrose Earl Edgerton; William Friedberger; *L. J. Schermerhorn; Hudson Smythe*; Norman E. Williamson. TRACY—Sydney Ernest D. Pinniger.

San Luis Obispo County

PASO ROBLES—Alvin Hillis Wilmar. SAN LUIS OBISPO—Roy Milo Cox; Byron Young Miller; Paul Kinsley Jackson.

San Mateo County

BURLINGAME—Herbert Seth Anderton; Henry Stevens Kiersted. SAN MATEO—Wood Carson Baker; Walter C. Chidester; Albert Cohen.

Santa Barbara County

GUADALUPE—John Henry Franklin. SANTA BARBARA—Rexwald Brown; Philip S. Chancellor; Gilbert Van Tassell Hamilton; Charles Lynn Morris; Harold Sidebotham; Alexander C. Soper.

SANTA MARIA—Lambert B. Coblentz.

Santa Clara County

AGNEW—Glenn E. Myers. LOS ALTOS—Wladimir Feodor De Niedman. LOS GATOS—George Moulthrop Hubbell. MAYFIELD—Franklin Monroe Seibert.

PALO ALTO—Herlwyn Ruggles Green; Henry Power; Harry Badger Reynolds; Benjamin Thomas.

SAN JOSE—Thomas Loftin Blanchard; Charles Benjamin Hare; Henry D. Hubbard; Frank H. Paterson; Charles Maynard Richard; Lester Charles Scully. SARATOGA—George Waldo Burgess. STANFORD UNIVERSITY—Jaime de Angulo; William Freeman Snow; Herbert Rowell Stolz. SUNNYVALE—George Peter Hall.

Santa Cruz County

DAVENPORT—Bartholomew Gattuccio. SANTA CRUZ—Ben Howard Bush; William Joseph Hosford; Charles Hadden Parker; Alfred Liles Phillips.

Shasta County

REDDING—Ernest Dozier.

Sierra County

ALLEGHANY—John Gustav Norman.

Siskiyou County

MONTAGUE—Charles Plus.

Solano County

BENICIA—Francis Marion Wall. DIXON—Otto Philip Floreth; Henry E. Morrison. VACAVILLE—Humphrey P. Palmer. VALLEJO—Edward August Peterson.

Sonoma County

ELDRIDGE—Fred Otis Butler. PETALUMA—James Garfield Anderson; John Thomas O'Brien; Stuart Zeno Peoples. SANTA ROSA—Jackson Temple. SEBASTOPOL—Lafayette J. Wilson.

Stanislaus County

MODESTO—Robert W. Brace. OAKDALE—Bert Lee Doane; Cecil Ephraim Smith; J. Audley Young.

Tehama County

CORNING—Alonzo Des Moines Snyder.

RED BLUFF—Frank L. Doane.

Trinity County

TRINITY CENTER—Wm. Arthur Rowell.

WEAVERVILLE—David Blackstone Fields; Llewellyn George Petch.

Tulare County

EXETER—Alexander David McLean; Pernier Albert Mix. LINDSAY—Gordon Adams Clapp; Herbert Ronald D. Shoemaker. PORTERVILLE—*Harry Josiah Willey. WOODLAND—Fred Ross Fairchild.*

Tuolumne County

SONORA—George Chauncey Wrigley.

Ventura County

OJAI—Jerome Tewksbury Gardner. OXNARD—Ralph Washburn Avery; Frank Joseph Tillman. SANTA PAULA—Gavin Shearer Herbert; Benjamin Eugene Merrill. VENTURA—Ralph W. Homer; William Joseph Lewis.

Yolo County

DAVIS—Charles Edward Schoff.

Yuba County

CAMPTONVILLE—Frederick King Lord. MARYSVILLE—Everett Edwin Gray; Fred Boyd Tapley.

COLORADO STATE MEDICAL SOCIETY

Officers 1917-18

Edward Jackson, President ....Denver
Peter Hanford, First Vice President ....Colorado Springs
J. H. Bush, Second Vice President ....Sterling
B. B. Blotz, Third Vice President ....Rocky Ford
Chas. Trueblood, Fourth Vice President ....Monte Vista

Councilor Districts and Officers

First District.—Boulder, Larimer, Grand, Weld, Logan, Sedgwick, Phillips, Morgan, Washington and Yuma Counties. J. A. Matlock, Longmont, and M. R. Fok, Sterling, Councilors.

Second District.—Gilpin, Clear Creek, Jefferson, Denver, Arapahoe, Adams [illegible] Counties. Horace G. Wetherell, Denver, and J. W. [illegible]ncilors.

Thir[illegible]eller, Fremont, El Paso, Lincoln, Kit Carson, Cheye[illegible] Pueblo, Otero, Kiowa, Bent, Prowers, Huerfano, [illegible] Counties. W. H. Swan, Colorado Springs, and E. A. Elder, Denver, Councilors.

Fourth District.—Delta, Mesa, Lake, Ouray, Montrose, Chaffee, Rio [illegible] Garfield, Eagle, Rio Blanca and Routt Counties. H. S. [illegible]unction, and Samuel French, Meeker, Councilors.

[illegible]nnison, Pitkin, Saguache, Costilla, Conejos, Mineral, [illegible] San Juan, La Plata, Montezuma, Dolores and San Miguel Counties. A. R. Pollock, Monte Vista, and Edgar Hadley, Montrose, Councilors.

1. Includes Jacksonville, population 73,137; physicans 175 [M.R.C. 42].
2. Flagler county was recently formed from parts of St. John and Volusia counties. The 3 counties have 1 physician for every 33.7 square miles and for every 602 people.
3. Includes Tampa, population 51,521; physicians 93 [M.R.C. 17].
4. Okeebochee county was recently formed from parts of Osceola, Palm Beach and St. Lucie counties. The 4 counties have 1 physician for every 135.1 square miles and for every 756 people.

son; Carey Pegram Rogers; Wm. Riley Schnauss; Elijah Thomas Sellers; Raymond C. Turck; Howard Crawford Von Dahm; Albert Harrison Wilkinson.

PANAMA CITY—John Marion Whitfield. LAKE CITY—Daniel Benj. Williams.

Escambia County

CENTURY—Neece Lewis Gachet; John Samuel Turberville. MUSCOGEE—Robert Hardy Trammell. PENSACOLA—Allen Monte Ames; James Henry Bickerstaff; Fritz A. Brink; Herbert Lee Bryans; Thomas Jesse Busey; Clinton Willoughby D'Alemberte; Hyman Max Ginsberg; John Whiting Hargis; Frank Petty Hixon; Stephen Russell Mullory Kennedy; Daniel McMillan; Joseph Arnold Mixon; David C. Thompson. PINE BARREN—William Arthur Clark. WALNUT HILL—Herbert Arent McClure.

Franklin County

APALACHICOLA—Frank Fenton Ferris.

Gadsden County

CHATTAHOOCHEE—Ralph N. Greene. QUINCY—Harry Bernard McEuen. REDDICK—Robert Donald Ferguson.

Hillsborough County

FT. DADE—John K. Hereford. PLANT CITY—John Walker Alsobrock; James Wilhite Crum. TAMPA—[illegible] Robert Edgar Baldwin; Andrew Robeson Bond [illegible] ıd F. Carlton; Geo. Bailey Coon; Lester Julian [illegible] Gilmer; John Halliday; Thomas R. Jones; William Jesse Lancaster; Leonard G. Larner; John Donald MacRae; Raymond B. McClaws; Earle H. McRae; Lucian Bayard Mitchell; J. Brown Wallace.

Holmes County

CHATTAHOOCHEE—John D. Gable.

Jackson County

MARIANNA—Daniel C. Campbell.

Jefferson County

MONTICELLO—James Ragan McEachern.

Lafayette County

ALTON—Walter Joseph Baker; Percy Herbert Brigham.

Lake County

CLERMONT—Joseph Haskell Chiles; John Alfred Newham. LEESBURG—Tucker Lucas Randolph. SORRENTO—Shores Erastus Clinard; Osmer Lionel Callahan. TAVARES—Sanford Carl Colley.

Lee County

BOCOGRANDE—George Elliott Atwood. FORT MYERS—Henry Elliott Parnell.

Leon County

MICCOSUKEE—Edgar Eugene Strickland. TALLAHASSEE—George Humphrey Gwynn Jr.; Humphrey Wilson Gwynn; John Kent Johnston; Otis Gilben Kendrick; Frederick Clifton Moor.

Levy County

WILLISTON—Grover C. Freeman. OTTER CREEK—Robert Francis McLeod.

Liberty County

HOSFORD—Kenneth McCaskill Davis; Sterling Edwin Wilhoit.

Madison County

GREENVILLE—Loren A. Greene; Angus James Smith. MADISON—Eustace Long.

Manatee County

BRADENTOWN—Samuel G. Hollingsworth. MYAKKA CITY—Frank R. Haura. PALM BEACH—Owen Hill Kenan. PALMETTO—MacMiller Harrison; Bedford Eugene Vaughan. SARASOTA—John Halton; Frederick William Schultz.

Marion County

CITRA—Everard Blackshear. DUNNELLON—Robert Creswell Black. McINTOSH—Adam Clark Walkup. OCALA—Wallace P. Crigler; Henry C. Dozier; Frank Elmer McClane; Harry Farlin Watt.

WEIRSDALE—Wince A. J. Johnon.

Monroe County

KEY WEST—Frank E. Artaud; George Rochefoucauld Plummer; Joseph Y. Porter Jr.; William R. Warren.

Orange County

ORLANDO—Harold M. Beardall; Milne Barker Swift.

Osceola County

KISSIMMEE—Hugh St. Clare Geiger.

Pasco County

TRILBY—Harvey Otis Byrd.

Pinellas County

CLEARWATER—James W. Davidson; Lucian Brown Dickerson. PASSA-GRILLE—Claude Vernon Gautier. ST. PETERSBURG—Morton H. Asline; Ludlow Lambdin; John William McClane; George Merrill Randall. TARPON SPRINGS—Ralph Dollahan Murphy; Willie Joseph Vinson.

Polk County

BARTOW—Heber Peacock Newman; Knowles Gittings Oglesby. HAINES CITY—Holden E. Cline. LAKELAND—Ralph Duffy; John D. Griffin; William Rowan Groover; William Benjamin Moon; Willis Herman Watson. MULBERRY—Paul Lewis Goss. NICHOLS—Walter Philip Dickinson; Alex M. C. Jobson.

Santa Rosa County

PACE—John Calvert Holley. MILTON—Zebulon V. Johnston.

Seminole County

SANFORD—Thomas Albert Neal; Ralph Edwin Stevens.

St. John County

ST. AUGUSTINE—James Burnie Griffin; Maurice Eby Heck; Jacob John Spencer.

St. Lucie County

FORT PIERCE—Benjamin Leland Whitten.

Sumter County

BUSHNELL—Roscoe Conkling Hubbard. OXFORD—Roy H. Bryant.

Suwanee County

LIVE OAK—Archie Cowan Watson. WELLBORN—George Sterling McClellan.

LIVE OAK—William C. White.

Taylor County

BLUE CREEK—George William DuPree. LOUGHRIDGE—Ralph James Greene.

Volusia County

DAYTONA—J. E. Rowlings; Roy Howe. DE LAND—Robert Fairleigh McDaniel; John MacDiarmid.

NEW SMYRNA—Roy Roswell Niblack.

MEDICAL ASSOCIATION OF GEORGIA

Officers 1917-18

Eugene E. Murphey, President..........Augusta
R. D. Little, First Vice President..........Thomasville
E. C. Thrash, Second Vice President..........Atlanta
Wm. C. Lyle, Secretary-Treasurer..........Augusta

Councilor Districts and Officers

First District.—Burke, Jenkins, Screven, Bullock, Effingham, Tattnall, Bryan, Chatham, McIntosh and Liberty counties. A. J. Mooney, Councilor, Statesboro.

Second District.—Calhoun, Dougherty, Early, Baker, Mitchell, Miller, Dectaur, Thomas, Worth, Colquitt, Grady and Tift counties. C. K. Sharp, Councilor, Arlington.

Third District.—Taylor, Macon, Terrell, Schley, Sumter, Dooley, Lee, Stewart, Clay, Quitman, Crisp and Randolph counties. V. O. Harvard, Councilor, Arabi.

Fourth District.—Carroll, Heard, Coweta, Troup, Meriwether, Harris, Talbut, Muscogee, Marion and Chattahoochee counties. H. W. Terrell, Councilor, La Grange.

Fifth District.—Douglass, Fulton, DeKalb, Rockdale and Campbell counties. W. L. Champion, Councilor, Atlanta.

Sixth District.—Fayette, Henry, Spalding, Butts, Pike, Upson, Monroe, Jones, Bibb, Clayton, Crawford and Jasper counties. J. O. Elrod, Councilor, Forsythe.

Seventh District.—Dade, Walker, Catoosa, Whitefield, Murray, Chattooga, Gordon, Floyd, Bartow, Polk, Haralson, Paulding and Cobb counties. E. M. Bailey, Councilor, Acworth.

Eighth District.—Franklin, Hart, Madison, Elbert, Clarke, Oglethrope, Oconee, Wilkes, Morgan, Greene, Walton, Putnam and Newton counties. W. E. McCurry, Councilor, Hartwell.

Ninth District.—Fannin, Union, Townes, Rabun, Gilmer, Lumkin, White, Habersham, Pickens, Dawson, Hall, Banks, Cherokee, Forsythe, Jackson, Milton, Gwinnett and Stephens counties. L. C. Allen, Councilor, Hoschton.

Tenth District.—Taliaferro, McDuffie, Lincoln, Hancock, Jefferson, Richmond, Wilkinson and Baldwin counties. J. A. Price, Councilor, Milledgeville.

Eleventh District.—Appling, Jeff Davis, Irwin, Coffee, Wayne, Brooks, Clinch, Echols, Ware, Charlton, Pierce, Camden, Glynn, Berrien, Lowndes, Ben Hill and Turner counties. J. G. Tuten, Councilor, Jesup.

Twelfth District.—Dodge, Emanuel, Houston, Johnson, Laurens, Montgomery, Pulaski, Telfair, Toombs, Twiggs and Wilcox counties. E. T. Coleman, Councilor, Graymont.

HONOR ROLL

Adair County

FONTANELLE—Ira James Gibson. GREENFIELD—Earl Owen Reynolds.

Adams County

PRESCOTT—William Henry Clary.

Allamakee County

POSTVILLE—Otto James Blessin. WAUKON—Cecil G. Morehouse.

Appanoose County

MORAVIA—William Harris. MYSTIC—Laurell L. Lugar.

Audubon County

AUDUBON—Daniel Francis Mathias.

Benton County

BELLE PLAINE—*Don Hamilton Newland; Carl John Snitkay; George* William Yavorsky. BLAIRSTOWN—Raymond Alvah Seiler.

Blackhawk County

CEDAR FALLS—Thomas Johannes Heldt. WATERLOO—Elmer I. Dunkelberg; Leo Erwin Evens; Ben C. Everall; William Henry Jenks Jr.; Guthrie McConnell.

Boone County

BOONE—Mark Clyde Jones; Ben Tallman Whitaker.

Bremer County

SUMNER—Edwin Edward Wuttke. WAVERLY—Robert Henry Lott.

Buchanan County

INDEPENDENCE—Fred F. *Agnew; Henry Clemend Allen; Percy* B. Battey; Roy C. Jackson; Samuel Connell Lindsay; Judd Campbell Shellito. JESUP—Frank E. Shimer.

Buena Vista County

REMBRANDT—William Marvin Hubbard. STORM LAKE—James Horatio O'Donoghue.

Butler County

NEW HARTFORD—Dyre Henry Pelletier.

Calhoun County

LOHRVILLE—Edgar R. Earwood. MANSON—Thomas Blanchard Herrick; Hugh Mullarky. ROCKWELL CITY—Lewis Edward Eslick; Jefferson Newton Holt.

Carroll County

BREDA—Edward Webster Bookhart. CARROLL—Milton Joseph Freeman. DEDHAM—Cecil Claude Bowie. TEMPLETON—Otis Philip Morganthaler.

Cass County

GRISWOLD—Harrison L. Wyatt. MARNE—Chas. Walter Lyon.

Cedar County

DURANT—Julius Lewis Shryer. LOWDEN—Albert John Charlton. MECHANICSVILLE—Frank Albert Priessman.

Cerro Gordo County

CLEAR LAKE—Albin Blackmore Phillips. MASON CITY—William Jacob Egloff; Charles Lemuel Marston; James Edward McDonald; Frank G. Murphy; Stephen Ambrose O'Brien; Burton French Weston; Burton Raymond Weston. ROCKWELL—John Francis Meany.

Cherokee County

CHEROKEE—Prentiss Bowden Cleaves; Richard Gardner Eaton; William Arthur Howard; Morley Daniel McNeal; Fisher B. E. Miller; Love Elree Pennington; LeRoy Anderson Wescott.

Clay County

SPENCER—Roscoe Durr Taylor.

Clayton County

FARMERSBURG—Jesse Clifford Ross. McGREGOR—William Harper Thomas. MONONA—Kinsley Renshaw. STRAWBERRY POINT—George Earl Hesner.

Clinton County

CLINTON—David Sturgess Fairchild Jr.; Kurt Jaenicke; Edward L. Martindale; Harry Rogers Reynolds; Elmer Paul Weih. DE WITT—Morton Lyon. LOST NATION—Raymond Eugene Robinson.

LOW MOOR—Ralph Frank Luse.

Crawford County

CHARTER OAK—George Ray Hill; Thomas Frederich Thomsen. MANILLA—Walter E. Draper. WESTSIDE—Charles Luther Patterson.

Dallas County

ADEL—Harry Clay Irvin. DE SOTO—Martin T. Brewer. PERRY—Christian Henry Dewey; Henry Irl McPherrin; Harry Blaine Wilkinson. REDFIELD—Henry Edward Kleinberg. WOODWARD—Thomas Lee Long.

PERRY—Arthur James Ross.

Davis County

BLOOMFIELD—Paul Francis Guernsey; Charles Dalton Shelton.

Decatur County

LEON—Clairemont Hogue Mitchell. LAMONI—Oscar Hedberg Peterson; Paul Forrey Stookey.

Delaware County

GREELEY—Walter W. A. Kresensky. MASONVILLE—Leonard James Bowman.

Des Moines County

BURLINGTON—George B. Crow; Arthur Churchill Strong; Edward John Wehman.

Dubuque County

DUBUQUE—Arlie Vernon Bock; Lafayette Helmuth Fritz; Eugene Lewis; Dan Laurence Mahoney; Harry Caldwell Parker; Alanson Madison Pond; Edward Harvey White.

Emmet County

RINGSTED—James Kaykendale Guthrie. WALLINGFORD—Thomas Vincent Golden.

Fayette County

HAWKEYE—Thomas Nelson Walsh. OELWEIN—Dan William Shine. WAUCOMA—Walter Henry Fox. WEST UNION—Thomas Andrew King; Frank Beach Whitmore.

Floyd County

CHARLES CITY—William Leihton Griffin. NORA SPRINGS—Oscar Herman Banton.

Franklin County

HAMPTON—George Frederick Johnston; Howard Hubbard Johnston.

Fremont County

HAMBURG—Royal Clark Danley. SIDNEY—Audley Emmet Nelson.

Greene County

GRAND JUNCTION—Andrew Irvin Reed. JEFFERSON—Benjamin Charles Hamilton Jr.

Hamilton County

STRAFFORD—Carl Kall. WEBSTER CITY—Robert Cochran Crumpton; Franklin Joseph Drake; Ward Hannah; Everett Eugene Richardson. WILLIAMS—Francis Stephen Carey.

Hancock County

BRITT—Walter Simmons Chester; Edward Alexander Couper. CORWITH—Rollin Slosson Fillmore Jr. GARNER—George Arthur Bemis.

Hardin County

ACKLEY—James W. Thornton. IOWA FALLS—Clarke W. Mangun; Clarence McCarty Wray. NEW PROVIDENCE—Garnet Smith Felt. STEAMBOAT ROCK—J. Willard Caldwell.

Harrison County

LOGAN—Hans Hansen. MODALE—Amos V. Cooper. MONDAMIN—Walter George Finley; Donald H. Pitts. WOODBINE—Haramont Nathaniel Anderson.

Henry County

NEW LONDON—Frank Raymond Mehler. SALEM—Edgar Allen Stewart.

Howard County

CHESTER—Andrew Clinton Hansen. CRESCO—William Thomas Daly; George A. Plummer. LIME SPRINGS—Herbert William Plummer.

Humboldt County

BRADGATE—Frank Harold Gaffey. LIVERMORE—John Joseph Bowes; Paul Nicolai.

Ida County

BATTLE CREEK—James McAllister; Eugene W. Wolcott. IDA GROVE—Edward S. Parker.

Iowa County

MARENGO—Ira Nelson Crow. MILLERSBURG—Louis Burton Amick. NORTH ENGLISH—Ulysses Simpson Geiger; Harry Jacob Jones. WILLIAMSBURG—Irvin John Simi.

Jackson County

ANDREW—Leslie Worthington Rantz. BELLEVUE—John Chase Dennison. MAQUOKETA—Louis B. Carson; Stuart Howard Bowman; Frederick J. Swift. MILES—William Darwin McFaul.

Jasper County

MONROE—John Wm. Billingsley. NEWTON—Charles Everett Moore. PRAIRIE CITY—Clyde Randolph Van Voorhis.

KELLOGG—John Thomas Hanna.

Jefferson County

BATAVIA—John H. Baldridge. FAIRFIELD—James Frederick Clarke; Lora Douglas James.

Johnson County

IOWA CITY—Howard Lombard Beye; Thomas Roy Gittins; John B. Gregg; Edwin Elmer Hobby; Harry Rogers Jenkinson; Leo Arthur Nelson; James Joseph Rock; Jason Ned Smith; Elliott Sheldon Stong; Thomas Harrison Van Camp; Clarence Van Epps; Herman LeRoy Von Lacklom; George John Wenzlick; Theodore A. Willis. MT. VERNON—Herbert Rappael Mills; Edwin Cleveland Yoder.

Jones County

ANAMOSA—Clyde Leslie Van Patten. OLIN—Seward White; Howard Moore Williamson.

MONTICELLO—Colin Caudonz Thomas.

Keokuk County

HEDRICK—Rex Vale Henry; James Arthur Porter. KEOTA—Roy Robert Miller. KESWICK—Alvah Negus. WHAT CHEER—Charles Burr Taylor.

Kossuth County

ALGONA—Walter Fraser; Evert Clarence Hartman.

Lee County

FORT MADISON—Walter Harry Grimwood; Robert Stollt Reimers; Frederick Warner Sallander; Frederick Louis Wahrer.

KEOKUK—W. Frank Brown; Frank Manley Fuller; Bruce Lock Gilfillan; Henry Arthur Gray; Clarence Horace Kinnaman; George Raymond Narrley; William Rankin; William P. Sherlock; Fred C. Smith. SUMMITVILLE—Jesse Lee Saar.

3. Includes Kansas City, population 96,854; physicians 155 [M.R.C. 24].

HONOR ROLL

Allen County

HUMBOLDT—Herbert M. Webb. IOLA—John M. T. Baskette; Omar L. Cox; Orestes Lucien Garlinghouse.
MORGAN—Lester Isaac Simpson.

Anderson County

GARNETT—Arthur Benjamin Cullum; Tarlton Ambrose Hood.

Atchison County

ATCHISON—Eugene John Bribach; Hugh Lester Charles; Charles Singleton Ferguson; Thomas Edward Horner; William Francis Smith. POTTER—Sam Monteith Myers.

Barber County

HARDTNER—John Elmer Hammer. HAZELTON—William Leonard Welch. KIOWA—George Robert Waite. MEDICINE LODGE—Thomas Adolphus Coleman.

Barton County

CLAFLIN—Herbert William Jury. ELLINWOOD—LeRoy J. Wheeler. GALATIA—Eugene Monroe Adkins. GREAT BEND—Edward King Lawrence; Clark William Zugg. HOISINGTON—Edward Henry Atkin.

Bourbon County

BRONSON—George Scott Lambeth. FORT SCOTT—John C. Lardner; John Franklin McGill. FULTON—Tiberius L. Jones.

Brown County

BAKER—Henry Herman Olsen. HORTON—Harry Leslie Goss; Harry James Harker.

Butler County

AUGUSTA—John Frazer Pattison. BENTON—Oscar Newton Lightner. DOUGLAS—Joseph Cook Bunten.

Chase County

ELMDALE—Franklin T. Johnson Jr.

Cherokee County

COLUMBUS—Harry H. Brookhart. MINERAL—Earl C. Lightfoot.

Clark County

ASHLAND—Ivan Roy Burket; Paul Congleton Carson; Milton Oscar Nyberg.

Clay County

CLAY CENTER—Ira E. Durant; Emanuel N. Martin; Edwin Clyde Morgan. WAKEFIELD—John Everett Hewitt.

Cloud County

CLYDE—Monte Louis Belot; Francis James Moffatt. CONCORDIA—Leo Eugene Haughey; Ross Eberhardt Weaver. JAMESTOWN—Hugh Duncan McGaughey.

Coffee County

BURLINGTON—Carl Calvin Culver; David William Manson; Henry T. Salisbury. GRIDLEY—Marcellus Lowery Stockton. WAVERLY—Frank C. Boggs.

Comanche County

COLDWATER—Wade Doster.

Cowley County

ARKANSAS CITY—Emanuel Harry Clayton; Milton Hahn; Richard Claude Young. CAMBRIDGE—Daniel Alcott Holland; Seth H. Martin. WINFIELD—Walter Parry Guy; Harold H. Jones.

Crawford County

ARCADIA—Joseph D. Pettet. ARMA—William Elmer Orr. CHEROKEE—Almonta Deaver Hays. GIRARD—Dwight Culver Smith. HEPLER Chas. Louis Mosley. McCUNE—Charles Chapin. MULBERRY—William Allen Parrish. PITTSBURG—Richard Collins Henderson; Walter J. Nichols.

Decatur County

DRESDEN—Fred Raymond Funk. JENNINGS—Henry Osmond Hardisty. NORCATUR—Joseph Watkins Spearing.

Dickinson County

ENTERPRISE—Harrison Washington Wright. HERINGTON—James Welch. HOPE—Charles A. Dieter. MANCHESTER—Dana O. Jackson.

Doniphan County

HIGHLAND—Herbert Homer Smith. TROY—Wilhelm Albert Gartner. WATHENA—John Goldsborough Swails.

Douglas County

LARNED—Cyril Evan Sheppard. LAWRENCE—Ralph E. Barnes; Harry L. Chambers; Charles Francis Ensign; Edmond Ray Keith; Henry St. Clair O'Donnell; Carl Phillips. LE COMPTON—Carey Caldwell Kerr. VINLAND—Charles Everett Yates.

Edwards County

KINSLEY—James Byron Donnell; Walter P. Stoltenberg; Lewis Milward Schrader.

Elk County

MOLINE—Edward Arlington Marrs.

Ellis County

ELLIS—Nathaniel Adair Kidd Jr. HAYS—Casper Joseph Middlekauff.

Ellsworth County

ELLSWORTH—Jirah Marston Downs; Robert Lee Hoffman; Benjamin H. Mayer.

Ford County

BUCKLIN—Alexander Breckenridge Scott. DODGE CITY—Eugene James Broderick; Noble Elmo Melencamp. SPEARVILLE—Leonidas T. Brown.

Franklin County

OTTAWA—George Washington Davis; Boyd Franklin Eye; Charles Benedict Stephens. RANTOUL—Charles Clifford Bennett. RICHMOND—Delmar H. Smith. WILLIAMSBURG—Warwick T. Brown.

Geary County

JUNCTION CITY—Walter A. Carr; Reuben Jay Elliott; Frederick William O'Donnell; Leonard Somerville Steadman. MILFORD—John R. Brinkley.

Gove County

GRAINFIELD—Guy H. Winslow.

Gray County

CIMARRON—Robert Gottfried Klein. INGALLS—Earl V. Adams. *MONTEZUMA—David Charles Munford.*

Greenwood County

CLIMAX—Herschel Ledger Hendricks. EUREKA—George Blaine Garrison. MADISON—James Milton Moore. SEVERY—Walter Allen Hodges.

Harper County

ANTHONY—C. Fremont Cronk; Benjamin Franklin Hawk; Clarence Edward Ressler.

Harvey County

BURRTON—Irl Edwin Hempstid. NEWTON—Harold M. Glover; Ralph C. Hartman; Ralph Harold Hertzler; John Lewis Peppers; John R. Scott; Lawrence Theodore Smith.

Jackson County

DENISON—William Law Wilmoth. HOLTON—Joseph Cook Shaw. MAYETTA—Charles Jay Bliss. SOLDIER—Joseph Richard Adams. WHITING—Guy R. McCreery.

Jefferson County

McLOUTH—Frank Schaeffer. NORTONVILLE—Tena L. Eyerly. PERRY—Arthur Leroy Weisgerber.

Johnson County

DE SOTO—*Alvan Maurice Fortney.* LENEXA—*Lewis G. Allen;* Clifford Calvin Neeselrode. OLATHE—Charles W. Jones. SHAWNEE—Walter Otto Quiring; George Washington Thume.

Kingman County

KINGMAN—Charles Willard Longenecker.

Labette County

EDNA—Charles Alfred Thomas. MOUND VALLEY—Robert M. Bennett; Otto Jarson Dixon. PARSONS—*Elmer E. Bowser; Paul Christmann;* John C. Cornell; Thomas Eugene Crump; Edmond Anderson Lodge; John Guirley Missildine; Arthur Richard Nash; John William Tinder.

Lane County

DIGHTON—Sebree Samuel McGinnis.

Leavenworth County

EASTON—Alonzo Ray Adams. LEAVENWORTH—Albert Leroy Brown; Charles Elliott Brown; Joseph Howard Langworthy; Philip Benjamin *Matz;* Charles James McGee; Fletcher Burr Taylor. NATIONAL MILITARY HOME—Samuel Adams; John A. Barker; John Langley Fryer; Frederick Edwin Kraft; Rezin Clark Shawhan.

Lincoln County

LINCOLN—George Malcolm Anderson; Malcolm Newlon; John Magruder Sutton.

Linn County

CENTERVILLE—George Franklin Porter. MOUND CITY—John Orum *Dingus.*

Logan County

OAKLEY—Charles Melbourne Miller.

Lyon County

AMERICUS—*John B. Brickell; Roy Hammond Edmiston.* EMPORIA—Clarence Clinton Harvey.

Marion County

FLORENCE—Leonard Sweete Wagar. HILLSBORO—Henry Daniel Brunig. MARION—John F. Coffman Jr.; Charles William Matlock. PEABODY—Edward Hinmen Johnson.

Marshall County

BEATTIE—Emory Howard Gist. MARYSVILLE—John B. Close; Edward Lawrence Wilson. WATERVILLE—George Isaac Thacher.

McPherson County

CANTON—Samuel Neal Mallison. GALVA—Lewis Marion Gore. McPHERSON—*C. Freeman Brubaker;* Andrew Engberg; Marvin Hall.

INMAN—Theodore Henry Aschmann.

Miami County

BUCYRUS—Gerald L. *McGonigle.* OSAWATOMIE. Benjamin F. Frazer; Bahnson Weathers. PAOLA—Jacob Henry Haldeman.

Mitchell County

CAWKER CITY—Kirk Patrick Mason. SIMPSON—George Jennings.

Montgomery County

CHERRYVALE—William Grant Norman; Myron Laverne White. INDEPENDENCE—Joseph S. Alford; Frank Winfred Shelton; Chester Orville Shepard. TYRO—Ira Bradford Chadwick.

COFFEYVILLE—Everett Wallace Johnson.

Morris County

COUNCIL GROVE—Arthur John Lewis; Morris Bigelow Simpson. DELAVAN—Logan Illk Evans. DUNLAP—Lewis Scott Harvey. DWIGHT—*George Edwin Brethour.*

Morton County

ELKHART—John Harvey Hansen.

Nemaha County

CENTRALIA—William George Bouse. CORNING—John Child Maxson. SABETHA—William Logan Carlyle; William Roy Dillingham; *Saml. M.* Hibbard; Frederick E. Wrightman. SENECA—Francis Franklin Carter; John Rudbeck.

Ellsworth; Theodore Williams Ely; Arthur Brewster Emmons; Henry Manning Emmons; Martin Joseph English; James Hill Erlenbach; Harold Clarence Ernst; Richard Spelman Eustis; Albert Whittier Fellows; John Francis Fennessey; Charles D. Fille Brown; Neil Augustus Fogg; John Hess Foster; Archibald McKay Fraser; Somers Fraser; Edward Henry French; Channing Frothingham Jr.; Arial Wellington George; James Henry Gettings; Albert A. W. Ghoreyeb; Norman Wilkinson Gillespie; Bernard Aloysius Godvin; Thomas R. Goethals; Joel Ernest Goldthwait; Harry Winfred Goodall; Timothy Francis Goulding; Gustave P. Grabfield; Louis Julian Grandison; Horace Gray; Hyman Green; Milo Chester Green; Robert B. Greenough; Allen Greenwood; Fred Clarke Gunter.

Gilbert W. Haigh; Frank Smith Hale; A. J. Hamilton; Burion Everett Hamilton; John W. Hammond; William John Hammond; Wilbert Clark Hardy; Torr Wagner Harmer; Carl Thorburn Harris; Abraham Haskins; David Morris Hassman; David Heffernan; Frank Wellington Hodgdon Jr.; Edward Marshall Hodgkins; Morris Hoffman; Charles Byam Hollings; Sanford Burton Hooker; Albert A. Horner; David Walker Houston Jr.; Joshua Clapp Hubbard; Henry T. Hutchins; Frederick Carpenter Irving; Sumner Waldron Jackson; Arthur Percy Janes; James C. Janney; John Greenwood Jennings; Herbert L. Johnson; Elliott Proctor Joslin.

En Young Kau; Arnold B. Kauffman; George F. Keenan; James Alphonse Keenan; Miner Raymond Kendall; Edward King; Frederick A. King; Robert James Kissock; William Fletcher Knowles; Henry Adolph Kreutzmann; Walter Brackett Lancaster; John William Lane; Thomas Hinckley Lannon; Wesley Terrence Lee; George Adams Leland Jr.; Samuel Albert Levine; Robert Williamson Lovett; Julian Dyer Lucas; Fred B. Lund; Moses H. Lurie; Henry Lyman; Arthur Bates Lyon.

Andrew Roy MacAusland; George Albert MacIver; Donald John MacPherson; John L. Mahoney; Henry Levi Mann; Henry Chase Marble; Searle Bisset Marlow; John Foley Martin; Frank William Marvin; Nathaniel Robert Mason; Patrick Thomas McCarthy; Charles Walter McClure; Francis Henry McCrudden; Cornelius Joseph McGillicuddy; Joseph H. McGuire; Peter G. McKenna; Lewis Steele McQuade; Philip McQuestion; James Howard Means; David Bernard Medalia; Leon S. Medalia; Edgar Matthias Medlar; Adelbert Samuel Merrill; George Richards Minot; Charles Galloupe Mixter; Samuel Jason Mixter; William J. Mixter; Howard Moore; Samuel Leslie Morris Jr.; William Reid Morrison; Almon Gardner Morse; Harris Peyton Mosher; Allen Thomas Moulton.

Kemp Prather Neal; Andrew Nichols III; Edward Hall Nichols; Edwin B. Nielsen; Frank Garm Norbury; Frank Roberts Ober; Harry Olin; Everard Lawrence Oliver; Richard Frothingham O'Neill; Stanley Hart Osborn; Howard Osgood; Robert B. Osgood; George Byron Packard Jr.; Francis Winslow Palfrey; George William Papen; Frederick Parker Jr.; Harold F. Parker; Villard Stephen Parker; Charles William Peabody; Francis Weld Peabody; Hamilton Chesley Perkins; Arthur P. Perry; Warren Martin Pettingill; Frank Piper; Charles Terrell Porter; Joseph Hersey Pratt; James Jackson Putnam Jr.

Alexander Quackenboss; Francis Minot Rackmann; Carlisle Reed; John Arnold Reese; Harold William Ripley; Wyatt Sanford Roberts; William Henry Robey Jr.; Charles Irvin Roderick; Edmund Augustus Rogers; Mark Homer Rogers; Milton Joseph Rosenau; Curtis M. Rosser; Benjamin William Rudman; Israel E[illegible]s Rudman; William Timothy Rumage.

Louis Francis Salerno; Arthur Forrest Sargent; Joseph Carr Savage; Alpha Reuben Sawyer; David D. Scannell; Joseph Walter Schirmer; George H. Schwarz; Andrew Watson Sellards; Clarence Wesley Sewall; Malcolm Seymour; Albert Abraham Shapira; John Holbrook Shaw; Edward B. Sheehan; Warren Sylvester Shields; Joseph Henry Shortell; Max Silverman; Frank W. Sleeper; Harry Caesar Solomon; Robert Fulton Souther; Horace Kennedy Sowles; Lesley Hinckley Spooner; Charles Booth Spruit; Henry Eugene St. Antoine; John Joseph Stack; Albert W. Stearns; Harold Wentworth Stevens; James Kent Stoddard; James L. Stoddard; James S. Stone; Louis Strahlmann; Edward Clark Streeter; Richard Pearson Strong; David Sussler.

John Houghton Taylor; William N. Tenney; John Jenks Thomas; Harold Grant Tobey; James Rockwell Torbert; Cassell Clark Tucker; Louis Joseph Ullian; Beth Vincent; Ludo Von Meysenbug; Ralph Alexander Warden; John Warren; Frederic Augustus Washburn; Joseph Treloar Wearn; Conrad Wesselhoeft; William Fessenden Wesselhoeft; Arthur J. White; Paul Dudley White; Thomas William Wickham; Frank P. Williams; Paul R. Withington; William Franklin Wood; John Dawson Roswell Woodworth; McIver Woody; Wade Stanley Wright; Edwin Theodore Wyman; Ernest B. Young.

BOSTON—Theodore H. Aschmann; Fletcher M. Colby; Paul Carroll Dennett; Paul Waldo Emerson; Rafe Nelson Hatt; Douglas Heath Nisbet; Panagiotis Nichel Papoulacos; Llewellyn Harrison Rockwell; Adolph G. C. Schmack; Frank Robert Sedgley; Lewis Mahlon Spear; Edward Bancroft Towne.

CHELSEA—Allan R. Barrow; Heiman Caro; Frank Hills Chase; Sydney Vernon Kibby; Charles D. Padan; Dallas Pond; Glen A. Sheppard; Dudley D. Shoenfeld; Sigmund Simons; Charles Henry Wilson. DEDHAM—Hollis Goodell Batchelder. FORT BANKS—Walter Midkiff Crandall. HYDE PARK—Charles A. Cullen. REVERE—Joseph Jacob Skirball; Louis Irving Skirball. WINTHROP—Ben Hicks Metcalf; Starr Abner Moulton; Raymond Brewer Parker.

Worcester County

ATHOL—Benjamin Whitney Gleason. BALDWINSVILLE—Walter Franklin Robie; Henry Louis Stick. CLINTON—James Joseph Goodwin. FITCHBURG—Aime Napoleon Fregeau; John H. Kearney; Wilfrid Teller LaFortune; Clayton Rogers Lane; Albert F Rodrick. GARDNER—Samuel Joseph Benoit; Herbert William Ellam; Gordon Brooks Underwood.

LANCASTER—Edward Francis Washburn Bartol; Chester C. Beckley. LEOMINSTER—Appleton Howe Pierce; Frederick Charles Shulties. MILFORD—Francis Stephen Caldicott. NORTH BROOKFIELD—Edward Francis Phelan. OXFORD—Robert Swan Fletcher. PRINCETON—Elisha Sears Lewis. RUTLAND—James A. Lyon. SOUTHBRIDGE—George William Tully. UXBRIDGE—John William Ledbury Jr.; George Thomas Little. WEBSTER—Bernard Louis Plouffe; Ernest Elmer Smith. WESTBORO—Ralph M. Chambers; James Alfred Gould; Walter Arthur Jillson; Roland Stephen Newton; Thomas Joseph O'Brien; Winfred Overholser; Melvin Harvey Walker Jr. WESTMINSTER—George Mossman. WICHENDON—William F. Holzer.

WORCESTER—Winthrop Adams; Howard W. Beal; Gordon Berry; Edward Bridge Bigelow; Alfred George Bolduc; Howard Spencer Colwell; George Henry Crofton; William Edward Denning; Kendall Emerson; Homer Gage; Frank W. George; Donald Robert Gilfillan; Samuel Carlton Gwynne; Frank Edwin Harriman; William Christian Jensen; Roger Kinnicutt; Willard Wallace Lemaire; George Chandler Lincoln; Merrick Lincoln; Israel Lurier; Frank Thorwald Oberg; Charles Augustus Salmon; Roger William Schofield; Edward Burnside Simmons; Hugh Ludwig Simmons; Willard Pierce [illegible] Armour Thom; John Clement Ward; George Watt; [illegible] Abraham K. Yoosuf.

GARDNER—Edw[illegible]
NORTH DANA—Charles Warner Robertson.
WESTBORO—Michael Matthew Jordan.

MICHIGAN STATE MEDICAL SOCIETY

Officers 1917-18

Andrew P. Biddle, President	*Detroit*
J. G. Turner, First Vice President	*Houghton*
J. Mersen, Second Vice President	*Holland*
A. O. Hart, Third Vice President	*St. Johns*
G. S. Ney, Fourth Vice President	Port Huron
Fredk. C. Warnshuis, Secretary	Grand Rapids
D. Emmett Welsh, Treasurer	Grand Rapids

Councilor Districts and Officers

First District.—Macomb, Oakland and Wayne counties. G. L. Kiefer, Councilor, Detroit.

Second District.—Hillsdale, Ingham and Jackson counties. A. E. Bulson, Councilor, Jackson.

Third District.—Branch, Calhoun, Eaton and St. Joseph counties. S. K. Church, Councilor, Marshall.

Fourth District.—Allegan, Berrien, Cass, Kalamazoo and Van Buren counties. A. H. Rockwell, Councilor, Kalamazoo.

Fifth District.—Barry, Ionia, Kent and Ottawa counties. W. J. Du Bois, Councilor, Grand Rapids.

Sixth District.—Clinton, Genessee, Livingston and Shiawassee counties. A. M. Hume, Councilor, Owosso.

Seventh District.—Huron, Lapeer, Sanilac and St. Clair counties. W. J. Kay, Councilor, Lapeer.

Eighth District.—Gratiot, Isabella-Clare, Midland, Saginaw, Tuscola counties (and Gladwin unattached). A. L. Seeley, Councilor, Mayville.

Ninth District.—Benzie, Grand Traverse-Leelanau, Manistee, Mason, Tri-counties (Kalkaska, Missoukee, Wexford). B. H. McMullen, Councilor, Cadillac.

Tenth District.—Bay (including Arenac and Iosco), Otsego, Montmorency, Crawford, Oscoda, Roscommon and Ogemaw combined. C. H. Baker, Councilor, Bay City.

Eleventh District.—Mecosta, Montcalm, Muskegon, Oceana, Newaygo, Osceola-Lake counties. W. T. Dodge, Councilor, Big Rapids.

Twelfth District.—Chippewa (including Luce and Mackinaw), Delta, Dickinson-Iron, Gogebic, Houghton (including Baraga and Keweenaw), Ontonagon, Marquette-Alger, Menominee and Schoolcraft counties. R. S. Buckland, Councilor, Barada.

Thirteenth District.—Alpena (including Alcona), Antrim, Charlevoix, Cheboygan, Emmet and Presque Isle counties. F. C. Witter, Councilor, Petoskey.

Fourteenth District.—Lenawee, Monroe and Washtenaw counties. C. T. Southworth, Councilor, Monroe.

HONOR ROLL

Allegan County

St un; Robert Page Stark; Howard Wallace
V ludnutt. PLAINWELL—Willard Robert
J. Walker.

Alpena County

ALPENA—Clarence Mason Williams.

Antrim County

ATWOOD—Bernard J. Beuker. CENTRAL LAKE—Edward Wilbur Vis. EASTPORT—Versile Mornington Gates. ELK RAPIDS—Louis Norman Yerkes. MANCELONA—Worth W. Walton.

Baraga County

PEQUAMING—Frank Fremont Marshall.

Barry County

DELTON—Maurice James Cross. MIDDLEVILLE—Birge Carlton Swift.

Bay County

BAY CITY—Frederick Smith Baird; Frank Winne Brown; Edward Goodwin; Edward Spaulding Huckins; Roy C. Perkins; Floyd H. Randall; Royston Earl Scrafford.

Berrien County

BARODA—Louis Andrew King. BENTON HARBOR—Myron Geo. Becker Jr.; Carl Apperson Mitchell; Warren P. Morrill; Burton Lewis Stevenson. BRIDGEMAN—David Littlejohn COLOMA—Spencer Van Barnum.

Branch County

COLDWATER—Wilbur Aaron Griffith. UNION CITY—Walter Wm. John Bien.

Calhoun County

ALBION—Edwin M. Chauncey; George C. Hafford. ATHENS—Elijah Van Camp.

BATTLE CREEK—James Thomas Case; James Adam Elliott; Robert Vincent Gallagher; Wilfred Haughey; Jesse James Holes; Awra Andrews Hoyt; Karl High Kellogg; Theodore Kolvoord; Asa Charles McCurdy; Willard Nichols Putnam; Kendall Brooks Rees; Albert Howard Ross; Leland Herbert Tower; Carl George Wencke. BEDFORD—Kendall Brooks.

Cass County

CASSOPOLIS—Edgar Clarence Dunning; Chas. Maxwell Harmon; James Henry Kelsey. DOWAGIAC—Walter Stokes Sharpe. MARCELLUS—Ralph Phillip Jones.

Charlevoix County

CHARLEVOIX—Allan Marshall Wilkinson. EAST JORDAN—Hugh William Dicken.

Cheboygan County

CHEBOYGAN—Arthur Julius Sahs. INDIAN RIVER—Lyle D. McMillan. MACKINAW—Allen Charles Tiffany. WOLVERINE—Archibald McKillop.

Chippewa County

FORT BRADY—Everett Allen Anderson. RUDYARD—Robert Douglass Scott. SAULT STE. MARIE—Emil Henry Webster; Rollin C. Winslow.

Clare County

CLARE—Arthur Robert Mussell; Burton Jay Sanford.

Clinton County

EUREKA—Myron Stephen Gregory. ST. JOHNS—Walter Abner Scott; Don Harry Silsby.

Crawford County

GRAYLING—J. Atwood Whitaker.

Delta County

ESCANABA—Harry J. Defnet; Victor Francis Ryan; Heming Oliver Lindholm; John Jos. Walsh. RAPID RIVER—John Lindsay Conover.

Dickinson County

CHANNING—Robert E. Hayes. FOSTER CITY—Gustavus W. Moll. IRON MOUNTAIN—Samuel Edwin Cruse.

Eaton County

CHARLOTTE—Stanley Allison Stealy. GRAND LEDGE—Wells Blakeslee Fillinger. VERMONTVILLE—Clyde L. D. McLaughlin.

Genesee County

CLIO—Benjamin Thomas Goodfellow. FLINT—Gordon Henry Bahlman; Chas S. Ballard; Myron William Clif; Henry Cook; Victor Henry de Somoskeoy; John W. Evers; George Reinhold Goering; Harry Clark Hackman; Wm. Henderson Marshall; Carl Frederick Moll; Ray S. Morrish; Arthur Venton Murtha; Robert Leo Phillips; George Kenneth Pratt; Herbert Elmer Randall; Floyd Albert Roberts; Walter Henry Winchester. GRAND BLANC—Wells Cook Reid. GOODRICH—Frederick J. Burt. SWARTZ CREEK—Albert Briton Clark; James Houston.

Gogebic County

IRONWOOD—Charles David Collins; Edward Hayes Kelly. WAKEFIELD—Theodore Suante Crosby; Donald E. MacPhail. WATERSMEET—George James Curry.

Grand Traverse County

TRAVERSE CITY—Wm. Daniel Mueller.

Gratiot County

ALMA—Cyrus Bunting Gardner; Arthur Alma McNabb. ITHACA—Clarence Edw. Burt.

Hillsdale County

HILLSDALE—Burt F. Green; Elihu Arthur Martindale; Harry Clay Miller. JONESVILLE—Ira James Stoner. LITCHFIELD—William Hodgines Atterbury. PITTSFORD—William Edward Alleger.

Houghton County

CALUMET—John Francis Barton; James Rubeo Lisa; Peter Duncan MacNaughton; John D. McKinnon; Bertram Henry Olmstead. DOLLAR BAY—Albert Roache Pearce; Raymond Moralee Schulte. HOUGHTON—William Roy Bridgman; Robert Bruce Harkness; Alfred C. LaBine. LAURIUM—Murdoch M. Kerr; James Rhines.

Huron County

PIGEON—Alfred Elihu W. Yale.

Ingham County

LANSING—Chauncy Levi Barber; Henry Shank Bartholomew; Wayne Alexander Cochran; Marshall L. Cushman; Marinus L. Holm; James Alton Humphrey; Ray Richmond McCrumb; Harold Abind Miller; Forest Ralph Ostrander; Arthur Elliott Owen; Milton Shaw. STOCKBRIDGE—L. A. Woodlock.

Ionia County

IONIA—Verner H. Kitson; Julius Henry Powers; Perry Christian Robertson. LAKE ODESSA—Frederick L. Morse; Nelson McLaughlin.

Iosco County

TAWAS CITY—Charles Vernor Crane.

Iron County

IRON RIVER—Wilhelm Carl Liefert.

Isabella County

BLANCHARD—Ralph Ernest Dawson; *Theodore Peter Vander Zalm.* MT. PLEASANT—Chas. D. Pullen.

Jackson County

BROOKLYN—Cortlandt Whitehead Schepeler. JACKSON—Warren Bradley Anderson; Herman Duane Brown; Randall N. Cooley; Cuthbert Earl De May; Chas. Rowse Dengler; *Harold Lee Hurley*; John Joseph McCormick; Miar John McLaughlin; James Andrew McQuillan.

Kalamazoo County

AUGUSTA—Robt. Eaton Weeks. KALAMAZOO—Ross Uriah Adams; Ralph E. Balch; Jerome Francis Berry; Orton H. Clark; Ward Eugene Collins; Leo J. Crum; Dan Holton Eaton; *Wm. Geo. Hoebeke*; Rosco G. Leland; Louis Desenberg Stern. *RICHLAND*—William Newton Kenzie.

Kent County

ADA—Raymond C. Breece. EAST GRAND RAPIDS—Fred Plumer Currier Jr.

GRAND RAPIDS—Louis Barth; Horace J. Beel; Henry M. Blackburn; Alexander M. Campbell; *Louis Henry Chamberlain*; John Ralph Coryell; Clyde Wilson Deaver; Willis L. Dixon; John Clinton Foshee; Howard A. Grube; John Thompson Hodgen; John Newell Holcomb; *Wm. Aloysius* Hyland; John Carl Kenning; Frank Cameron Kinsey; Milford Arthur *Leach*; Wm. De Voe Lyman; Wm. Robt. Manlove; *Alex. M. Martin*; *Louis Thomas O'Brien*; Henry John Pyle; Omer Roan; Leon Edmund Sevey; *Ansel Brooks Smith*; Richard Root Smith; Roland Egbert Toms; *Sumner Merill Wells Jr.*; Joseph Burgess Whinery; William E. Wilson. *LOWELL*—Aaron C. Button; *Hans Peter Gotfredsen*. GRANDVILLE—Jacob Daniel Brooks. SOLDIERS' HOME—Howard A. Grube.

Keweenaw County

MOHAWK—Albert Roling Tucker. PHOENIX—John Leo Kelliher.

Lenawee County

ADRIAN—Artemus Ward Chase; *Ara Bird Hewes*; Esli Terrill Morden; Leo John Stafford; Mahlon R. Sutton; George Mitchell Lochner. CLINTON—Robert Anthony Davis. DEERFIELD—Guy Malverton Claflin. MORENCI—Van Dale Barnes. ROLLING—John Leonard Meddaugh. SAND CREEK—William Henry Meddaugh.

ADRIAN—John Perry Bland.

CLINTON—Carroll Semans Thomson.

Livingston County

HOWELL—Vern N. Richesen. PARSHALLVILLE—William John Rynearson.

Macomb County

MT. CLEMENS—Henry G. Berry; Harold Arthur Kirkham; Charles Allen Martin; Harry Ferris Taylor; Russell William Ullrich; Arthur Jay Warren. ROMEO—Robert McKay Greenshields; Edgar J. Miller; Milton Case Smith. WASHINGTON—Curenus B. Lockwood.

ROMEO—Walter Robert Taylor Sharpe.

MEMPHIS—George Waters.

Manistee County

BEAR LAKE—Ward Herman Norconk. COPEMISH—Russell Ragan Huston. MANISTEE—Elmer Alfred Gunderson; Harlen MacMullen; Andrew A. McKay.

Marquette County

GWINN—David Christian Eisele. ISHPEMING—Albert V. Deventer Brrden. MARQUETTE—Howard T. Carriel; Roscoe Conkling Main; Harold Boyce Markham. MICHIGAMME—Isaiah Sicotte. NEGAUNEE—Ira A. Abrahamson; Emile Cyrus Houle.

Mecosta County

BIG RAPIDS—Wm. Temperance Dodge; Rolla George Karshner; Glen Dewey Ransom; Gordon Hurst Yeo.

Menominee County

MENOMINEE—Calvin Ross Elwood; Walter Raleigh Hicks; Stephen Codding Mason; Earl Vinton McComb; Henry Thomas Sethney.

HUDSONVILLE—George Eddie Johnson. POTTS CAMP—Robert Hugh Pegram.

Monroe County

ABERDEEN—James Milton Acker Jr.; Richard M. Boyd; Leonard; Andrew Crosby. *GATTMAN—Forney Know Hollis.* HAMILTON—Lewis Wheeler Darracott. MULDON—James Estelle Dunlap. SMITHVILLE—Victor Hugo Bean.

Montgomery County

DUCK HILL—Samuel S. Caruthers. *KILMICHAEL*—Henry Gooch Hammond. SWEATMAN—Frank Lynn McGahey. WINONA—John Woodson Barksdale; George Baskerville; Thomas Wilburn Holmes; William Jefferson Lusk; Zachariah James Scott.

Neshoba County

PHILADELPHIA—Charles Henry Harrison; William Carl Seale.

Newton County

CHUNKY—Charles Augustus Martin. HICKORY—J. R. Plummer. NEWTON—Augustus Melville Harrelson. UNION—Zeffa Carl Hagen.

Noxubee County

SHUQUALAK—John Howard Kellis.

Oktibehha County

AGRICULTURAL COLLEGE—Benjamin Joseph Marshall. STARKVILE—Fred Lee Ricks.

Panola County

PLEASANT GROVE—James Freeman Williamson.

Perry County

AGNESS—*Frank Aquilla* Rogers. NEW AUGUSTA—Benjamin Travis Robinson. *RHODES—Iris Joe Slay.* *RICHTON—Edward Moody* Gavin; David W. Walley.

Pike County

MAGNOLIA—*Rufus E.* Applewhite. *McCOMB—Eugene Ray Gordon;* Bryant Jefferson Hewitt; Luther Boyce Otken. SUMMIT—Kotz Allen.

Pontotoc County

ALGOMA—Edward Greenland Abernethy.

Prentiss County

BOONEVILLE—Franklin Gail Riley.

Quitman County

LAMBERT—Eric Alexander McVey.

Rankin County

PUCKET—Solomon *Relophard Boykin.*

Scott County

LAKE—William Edwin Moody.

Simpson County

MAGEE—Ernest Leonard Posey. PINOLA—John Lively White.

Sunflower County

BALTZER—Claud Clinton G[illegible] Estus Farmer. DREW—Bernard Hess *Booth.* [illegible] les Kent; George Jefferson Mancill; Samuel Doa[illegible] —Lee Kelly Mayfield. RULEVILLE—Burris Earle Burchfield.

Tallahatchie County

CHARLESTON—Hugh White Priddy. PHILLIPP—George Randolph Storm. TIPPO—Walter Clarence Friday. TUTWILER—John Garner Backstrom. WEBB—John Aaron Harris; William Robin Harris.

Tate County

STRAYHORN—*Lewis Wesley* Kitchens.

Tippah County

RIPLEY—John Taylor Barbee.

Tishomingo County

PADEN—Carl Western Norwood.

Tunica County

DUNDEE—Hal Glenn Johnson.

Union County

BLUE SPRINGS—William C. Hays. NEW ALBANY—Clyde Madison Speck; Hugh *Priddy* Boswell; William Luther Newton.

Walthall County

KNOXO—Richard Baker Austen.

Warren County

VICKSBURG—Hugh C. Denson; Charles John Edwards; John Sharp Ewing; Ewing Fox Howard; Sydney William Johnston; Richard Thomas O'Neil; Fred Edward Pinson; Henry Franklin Sproles; Augustus Street.

Washington County

BELZONI—Edw. L. Robertson. ERWIN—Walter William Scott. FOOTE—Thompson F. Worthington. GREENVILLE—John George Archer; Paul Gaston Gamble. HOLLANDALE—George Howard Spivey. ISOLA—William George Byrd; William Cooke Lester. WAYSIDE—Franklin Howard Russell.

Wayne County

CLARA—George David Mason.

Webster County

EUPORA—J. Howard Brown.

Wilkinson County

FORT ADAMS—David George Lemkowitz.

Winston County

LOUISVILLE—Silas Wesley Pearson. NOXAPATER—Joseph Cone Robinson. PLATTSBURG—James Henry Slaughter; Samuel Houston Wood.

Yalobusha County

COFFEYVILLE—Roger Pou Hentz. WATER VALLEY—Hilton Rice Carr; Montie Porter; Jesse Davis Westmoreland.

Yazoo County

BENTONIA—Miller Craft Henry. LAMKIN—James Sims Reid. LOUISE—James Thomas Rainer. MIDNIGHT—William Adam DeWitt James. VAUGHAN—John Houston Steen. YAZOO CITY—George Cameron Jones.

MISSOURI STATE MEDICAL ASSOCIATION

Officers 1917-18

Robt. E. Schlueter, President	St. Louis
Vice Presidents—	
J. P. Henderson	Kansas City
H. A. Lowe	Springfield
Frank B. Long	Sedalia
W. A. Clark	Jefferson City
F. W. Colton	Van Buren
E. J. Goodwin, Secretary	St. Louis
Gail D. Allen, Treasurer	Lamar

Councilor Districts and Officers

A. R. McComas, Chairman, Sturgeon; E. J. Goodwin, Secretary, St. Louis.

First District.—Holt, Atchison and Nodaway counties. Eugene L. Crowson, Councilor, Pickering.

Second District.—Buchanan and Andrew counties. O. C. Gebhart, Councilor, St. Joseph.

Third District.—Harrison, Worth, Gentry and DeKalb counties. G. W. Whitely, Councilor, Albany.

Fourth District.—Grundy, Sullivan, Mercer and Putnam counties. J. B. Wright, Councilor, Trenton.

Fifth District.—Clark, Scotland and Schuyler counties. J. R. Bridges, Councilor, Kohoko.

Sixth District.—Adair, Knox and Lewis counties. P. F. Cole, Councilor, Ewing.

Seventh District.—Shelby, Marion and Ralls counties. Jacob D. Smith, Councilor, Shelbina.

Eighth District.—Lincoln, St. Charles, St. Louis and Pike counties. Leander W. Cape, Councilor, Maplewood.

Ninth District.—Audrain, Boone, Howard, Callaway, Warren and Montgomery counties. A. R. McComas, Councilor, Sturgeon.

Tenth District.—Macon, Randolph and Monroe counties. Don A. Barnhart, Councilor, Huntsville.

Eleventh District.—Chariton, Carroll, Livingston and Linn counties. G. W. Hawkins, Councilor, Salisbury.

Twelfth District.—Platt, Clay, Ray, Clinton, Caldwell and Daviess counties. Spence Redman, Councilor, Platte City.

Thirteenth District.—Jackson County. F. E. Murphy, Councilor, Kansas City.

Fourteenth District.—Lafayette, Saline and Cooper counties. C. T. Ryland, Councilor, Lexington.

Fifteenth District.—Cass and Johnson counties. H. S. Crawford, Councilor, Harrisonville.

Sixteenth District.—Bates, Vernon, Barton, Cedar and Dade counties. E. N. Chastain, Councilor, Butler.

Seventeenth District.—Pettis, Henry, Benton, St. Clair and Hickory counties. W. J. Ferguson, Councilor, Sedalia.

Eighteenth District.—Miller, Moniteau, Morgan and Camden counties. J. B. Norman, Councilor, Tipton.

Nineteenth District.—Cole, Osage, Maries and Gasconade counties. S. V. Bedford, Councilor, Jefferson City.

Twentieth District.—Franklin County and St. Louis City. A. H. Hamel, Councilor, St. Louis.

Twenty-First District.—Jefferson, Ste. Genevieve and Perry counties. G. M. Rutledge, Councilor, Ste. Genevieve.

Twenty-Second District.—Scott, Madison, Cape Girardeau, Mississippi and Bollinger counties. Garnett S. Cannon, Councilor, Fornfelt.

Twenty-Third District.—Dunkin, Pemiscot and New Madrid counties. J. H. Timberman, Councilor, Marston.

Twenty-Fourth District.—Wayne, Ripley, Butler, Carter, Shannon and Stoddard counties. Wm. [illegible] ar Bluff.

Twenty-Fifth District.—[illegible] n and St. Francis counties. O. A. Smith, [illegible]

Twenty-Sixth District.—[illegible], Laclede and Dent counties. W. H. Breuer, Councilor, St. James.

Twenty-Seventh District.—Howell, Ozark, Oregon, Texas, Wright and Douglas counties. H. C. Shuttee, Councilor, West Plains.

Twenty-Eighth District.—Dallas, Greene, Lawrence, Barry, Stone, Christian, Webster, Polk and Taney counties. T. O. Klinger, Councilor, Springfield.

Twenty-Ninth District.—McDonald, Newton and Jasper counties. R. L. Wills, Councilor, Neosho.

1. Includes Albany, population 111,077; physicians 249 [M.R.C. 68].
2. Includes [illegible] 5,791; physicians 107 [M.R.C. 14].
3. Includes [illegible] physicians 61 [M.R.C. 8].
4. Includes [illegible] ,415; physicians 48 [M.R.C. 7].
5. Includes Elmira, population 41,278; physicians 79 [M.R.C. 12].
6. Includes Poughkeepsie, population 34,656; physicians 74 [M.R.C. 17].
7. Includes Buffalo, population 475,781; physicians 857 [M.R.C. 123].
8. *Includes Watertown, population* 30,404; physicians 52 [M.R.C. 5].
9. Includes Brooklyn, population 2,330,183; physicians 2,358 [M.R.C. 372].
10. Includes Rochester, population 264,714; physicians 461 [M.R.C. 77].
11. Includes Amsterdam, population 38,043; physicians 39 [M.R.C. 4].
13. Includes Niagara Falls, population 47,058; physicians 49 [M.R.C. 10].
14. Includes Utica, population 89,272; physicians 150 [M.R.C. 14].
15. Includes Syracuse, population 158,514; physicians 336 [M.R.C. 35].
16. Includes Troy, population 78,094; physicians 116 [M.R.C. 21]
17. Includes Schenectady, population 103,774; physicians 124 [M.R.C. 23].
18. Includes Mt. Vernon, population 40,291; physicians 62 [M.R.C. 10], also New Rochelle, population 39,192; physicians 53 [M.R.C. 14], also Yonkers, population 103,066; physicians 105 [M.R.C. 21].

HONOR ROLL

Albany County

ALBANY—Stanley Earl Alderson; William Dewey Allen; Jas. M. Archibald; Milton Aronowitz; Chas. L. Bailey; John Charles Brown; Leroy Joseph Butler; Byron Edwin Chapman; Harold Duncan Cochrane;

Erastus Corning; Leon Chas. Cote; Frederick Joseph Cox; Joseph A. Cox; Stephen Horace Curtis.

Charles Edmund Davis; Louis Joseph De Russo; Arthur Maultby Dickinson; Thobald Frederick Doescher; Joseph Levi Donhauser; Malcol Douglas; Edwin Lyon Draper; Loyal Linsey Dunlop..

Lawrence Joseph Early; Arthur Wells Elting; Otto Alois Faust; Emanuel Martin Freund.

Louis H. Gaus; Wm. Edwin Gazeley; John Giffen; Lemuel Whittington Gorham; Clarence Flack Graham.

Philip C. Hacker; Paul Tompkins Harper; Harold Colvin Harlland; Clinton Benjamin Hawn; John Edward Heslin; William Patrick Howard.

Thomas W. Jenkins; Harry Vincent Judge; James Henry Keeling; Wm. Geo. Keens.

Joseph Aloysius Lanahan; Joseph S. Lawrence; Harry Judson Lipes; Howard Eaton Lomax.

Andrew MacFarlane; Robert A. MacTaggart; Clarence Edmonds Mullens; Joseph Patrick O'Brien.

George W. Papen Jr.; Harold Artemus Peck; Abraham Max Rabiner; George Bradford Randall; John Joseph Randall; Theodore D. Reed; Conrad Aloysius Rissberger.

Henry L. K. Shaw; Byron Gray Shults; John Archibald Smith; John Forrest Southwell.

H. K. Tebbutt Jr.; Ralph Waldo Turner; Edgar Albert Vander Veer; James Newell Vander Veer.

Howard Lull Van Winkle; William James Wansboro; Arthur Hastings Wheeler; Linsly Rudd Williams.

COHOES—Wallace Jos. E. Aubry; Joseph Charles Edward Daunais; Richard Patrick Doody; Raoul Albert Herbert; Aloysius Dewitt Maby; James Henry Mitchell Jr.; Leslie Boyd Seaport; Arthur Edgar Smith; Clarence Howarth White. DELMAR—Thomas Milton Holmes. GUILDERLAND CENTER—Frank Hazelett Hurst. RAVENA—James Edward Maloney. SOUTH BETHLEHEM—Frank A. Augur. WATERVLIET—Chas. Augustus Krauss. WEST ALBANY—Earl Wayne Wilkins.

Allegheny County

ALFRED—Emerson Winfred Ayars. BELMONT—Ralph Elmer Robinson. BOLIVAR—Laurence Hackett. CANASERAGE—Carl Geo. Schwan. CERES—Frederick John Pfisterer. CUBA—Theron Blain Bond. FRIENDSHIP—Harold MacMurray Johnson. RUSHFORD—Hanford Kendall Hardy. WELLSVILLE—Ray M. Eaton; Frederick Eugene McCarty.

Broome County

BINGHAMTON—Samuel M. Allerton; Carleton T. Bagley; Raymond Gernand Bell; Myer Sol. Bloom; John D. Bowen; John Groat Corson; Don M. Hooks; Harry Isaac Johnston; Ulysses Silver Kann; Sylvanus James Nunn; Frank W. Sears; Charles Anthony Squires. ENDICOTT—Dwight Guilford Dudley; James Santee McNett. JOHNSON CITY—John Walter Farrell. PORT DICKINSON—George Jesse Ganow. UNION—Ray Holly Humphrey.

BINGHAMPTON—Daniel C. O'Neil; Lester E. Sanford.

Cattaraugus County

ALLEGANY—Jay Gould. DELEVAN—Myron Everett Fisher. EAST RANDOLPH—James Edgar Crossman. GOWANDA—Herman Walter Johnson; Ira Warner Livermore; Frederick Perlee Schenkelberger. OLEAN—James Jay Clark; Clarence Albert Greenleaf; John Alexander Johnson Jr.; Raymond Bartlette Morris; Benjamin Van Campen. PERRYSBURG—Arthur Burt Graves. SALAMANCA—John Conrad Hoeffler; Charles Arthur Lawler; James Almon Taggert; George Beckwith Ubel.

ALLEGHENY—Eugene Daniel Quinlan.
OLEAN—Donald Angus MacDuffie.

Cayuga County

AUBURN—Francis Joseph Bennett; Eugene Napolean Boudreau; John Wordsworth Copeland; Raymond Fleming Johnson; Wm. Henry Kober Jr.; Rob Roy McCully; Forest Ray Mildren; Maxwell Kemper Willoughby. WEEDSPORT—Clinton Eddy Goodwin.

Chautauqua County

CASSADAGA—Henry Salem Edmunds. DUNKIRK—George R. Irving; Henry Jos. Meister; Norman Leo Sheene; Walter Hall Vosburg; John Charles Webster. FREDONIA—Roy John Juhre; Harry Elmer Wheelock. FREWSBURG—Francis John McCullo. JAMESTOWN—Frank Perry Goodwin; Floyd Warner Hayes; Walter G. Hayward; Edward Laban Hazeltine; Bergen Fred Illston; Milton John Johnson; William Miller Sill. KENNEDY—George William Batt. RIPLEY—Paul Sterrett Persons. SHERMAN—Guy Granger; Harold Elliott Shaver. WESTFIELD—Gunni Julius Busck; Roswell Fellows Foster.

Chemung County

ELMIRA—Floyd Pinckney Breese; Charles Hendry Erway; Arthur Clair Glover; Floyd Harding Jones; Louis Eugene McCanna; Edgar Warden Phillips; Stewart Stow Piper; Daniel Edgar Pugh; Arthur C. Smith; Donald Joseph Tillon; Raymond A. Turnbull; Bert Grant Voorhees. VAN ETTEN—Benjamin Franklin Colegrove.

Chenango County

GUILFORD—Blinn A. Buell. LINCKLAEN—Frederick Dudley Keppel. NORWICH—Edwin Fred Gibson; William Edward Hartigan. OXFORD—Burton Alexander Hall. SHERBURNE—Archibald K. Benedict. SMYRNA—Leroy Dilmore Soper. SOUTH OTSELIC—Jaynes Mott Crumb; Archibald Thomas Perkins.

Clinton County

DANNEMORA—Harold Russell Robert. PLATTSBURG—Wilmarth S. Buck; Le Roy Walter Hyde; Thomas A. Rogers; Ira Alonzo Rowlson; Willard Cornelius Thompson. STANDISH—Fred Vosburgh.

Columbia County

HUDSON—[illegible] Bradley; John Lounsbery Edwards; Henry [illegible] HOOK—Nathan David Garnsey. NEW LEB- [illegible] Brooks. OLD CHATHAM—Hamilton Munn [illegible] ohn Christian Knapp. STOTTVILLE—Jere- [illegible] Redmond Dimock.

Cortland County

CORTLAND—James J. Parsons; Daniel Robert Reilly. VIRGIL—John Harry Evans.

Delaware County

DELHI—Grover Asa Silliman. DOWNSVILLE—Fred De Grande Wilson. SIDNEY—Ralph Henry Loomis.

Dutchess County

BEACON—Leo Charles Dubois; Joseph Waldron Moore; George T. Polk; George Aaron Sharp. LAGRANGEVILLE—Ralph Grace. MILLBROOK—Vincent Valens McCabe. MILLERTON—Geo. Roger Dempsey. POUGHKEEPSIE—David T. Brewster Jr.; Grady Sebastian Clinkscales; Lawrence Edward Cotter; Charles D. Cromwell; St. Clair Terra Darden; Howard Wilcox Davis; Percy Loraine Dodge; James Taylor Harrington; Clyde Lipsey McNeil; Frederick Williams Parsons; Everett D. Plass; Arthur Grant Rodgers Jr.; Raymond Sanderson; Archibald Wilson Thomson; Lee Rose Tighe; Claude Evans Tubb; Sidney Chas. Vermilyea. STANFORDVILLE—John Newton Boyce.

WAPPINGER FALLS—Rowland Parker Blythe.

Erie County

BUFFALO—Francis Argus; Lloyd Kenneth Babcock; Antonio L. Barone; Peter Joseph Barone; Samuel Barone; Charles Joseph Barone; George Cosimo Barone; Herbert Henry Bauckus; Lynn Staley Beals; George Adam Becker; Edwin L. Beebee; Lawrence Melvin Belzer; A. L. Benedict; Maynard Gilmore Bensley; Joseph Barton Betts; Plynn Morton Bolton; Joseph Patrick Brennan; Jos. Brumberg; Patrick H. J. Buckley; Boleslaw M. Bukowski; Lorenzo Burrows Jr.

O. J. Case; Marshall Clinton; Julius Y. Cohen; Raymond Cleveland Conklin; George Ferdinand Cott; Harold Wm. Culbertson.

David M. Davis; Robert Edward DeCew; Richard Newnham DeNiord; Robert Paul Dobbie; Timothy Francis Donovan; Henry DeWitt Duryea.

Earl Leo Eaton; George J. Eckel; Albert Richard Ellison; John FitzGerald Fairbairn; Lee Francis Masten; Carl Grover Frost; Edward Lysander Frost.

Albert August Gartner; Harvey Russell Gaylord; George John Geisler; Milton Harry Goldberg; John C. Grabau; Irving Franklin Gram; Samuel Grienstein; John George Grotz.

Francis John Haley; George McK. Hall; Barton E. Hauenstein; Raymond Hensel; Wm. Oakley Hill; Robert W. Hinds.

Harold Bartlett Johnson; William Harry Jones; Daniel Jung; Russell Stewart Kidder; Robert King; Chas Gowen B. Klophel; Clarence Perry Kummer; Frank Kruse; Leon Sebastian Kurek.

Jos. Peter La Duca; Charles W. Lane; Sabrater C. Lojacono; Charles Edward Long; Frank Henry Long; Earl Henry Lormor; William Chisholm Lucas.

Walter Louis Machemer; Wallace F. MacNaughton; Baldwin Mann; Herman Frank May; William Lee McCanty; Arthur Everett McCarthy; Harold James McDonald; Hugh Chauncey McDowell; Descum Clayton McKenney; Michael James McMahon; Roland Otto Meisenbach; Edward Frederick Meister; John Anthony Metzen Jr.; Rudolph C. Miller; Vincent Chas. Moscato; Jerome Aloysius Murphy.

Joseph Aloysius Nowicki; Oscar J. Oberkircher; Geo. Melvin Oppermann; William Ostrow; Frederick Wm. Palmer; Charles C. Panzarella; Harold Alexander Patterson; William Ward Plummer; Frank Nelson Potts; Thomas H. Powick; Leon Hastings Prior.

Nelson Gorham Russell; Leo Marks Sachs; Arthur C. Schaefer; Charles Simon; Herbert Alexander Smith; Edward Archibald Southall; Frederick Edward Sperry; John Gurney Stowe; Fredk. Ettore Strozzi; Jas. Cornelius Sullivan.

Earl Wm. Thoma; Carl Tompkins; Haworth R. Traver; Alfred Herbert Vogt; Frank Gebhard Walz; John Henry Watson; Harry Milton Weed; Grover Wm. Wende; Carlton E. Wertz; Hiram Samuel Yellen. COLDEN—Warren Z. Dell. HAMBURG—Amos John Minkel. COLLINS—Herman Lester Raymond. LACKAWANNA—Harry Alexander Scott; Kenneth Allan Smith; Edward A. Twist. LANCASTER—Clarence Herbert Mackey. SPRINGVILLE — Gregory Everett Stanbro. TONAWANDA — Howard Cousins Fairbanks; Archibald William Thompson. WILLIAMSVILLE—Harry Bestow Huver.

BUFFALO—John Cunning Brady; Frederick William Filsinger; Urban Andrew Fischer; Harry Joseph Hammond; Thomas Henry McKee.

LACKAWANNA—Roy B. Woodward.

Essex County

AU SABLE FORKS—George Jacob Culver. KEESEVILLE—Frank M. Holcombe. PT. HENRY—Edward S. Smith. WESTPORT—John A. Battin.

Franklin County

BURKE—Frank Floyd Finney. CHATEAUGAY—Leonard Pearsons Sprague. MALONE—Benjamin Roy Allison. SARANAC LAKE—Edward Newman Packard Jr.; James Woods Price; Willard Burr Soper; Francis Berger Trudeau.

FRANKLINTON—Mack Canstuart King.

Gaston County

BELMONT—Charles Erwin McLean; John Mason Pressly. GASTONIA—Roland Smith Clinton; Lee Johnson. LOWELL—George Riddle Patrick. MT. HOLLY—*Burmah Dixon* Moore.

Gates County

SUNBURY—Harry Eskridge *Brooks.*
HOBBSVILLE—Thomas Leslie Carter.

Granville County

OXFORD—Benjamin Kingsey Hays; William Nelson Thomas.

Guilford County

GREENSBORO—Charles W. Banner; Joseph Henry Boyles; Walter Francis Cole; Booton Stover Compton; Mont Royal Farrar; Harold Roberts Lipscomb; John W. Long; *Herbert Hammond Ogburn*; *Adlai* Stevenson Oliver; Frederick James Pate; Henry Frank Starr; Julius *Graham Thomas.* HIGH POINT—John T. Burrus; Thomas Menees Stanton; Frederick Raymond Taylor. SUMMERFIELD—Newton Graves Wilson.

Halifax County

GARYSBURG—Wester Ghio Suiter. HOBGOOD—Virgil Wilson Leggett. ROANOKE RAPIDS—Daniel Frank Patchin. ROSEMARY—*Robert Payne* Beckwith. SCOTLAND NECK—Allie Dexter Morgan.

Harnett County

DUKE—Frank Rexborough Ruff. LILLINGTON—Laurie J. Arnold.

Haywood County

CANTON—Francis M. Davis; Wiley C. Johnson; Robert W. S. Ferram; Jesse M. Russell. SUNBURST—Burton *Barcett Sturdivant.* WAYNESVILLE—Joshua Fanning Abel; Joseph Howell Way.

Henderson County

EAST FLAT ROCK—B. F. Cliff.

Hartford County

AHOSKIE—Rack F. Benthall.

Hoke County

RAEFORD—Albert R. Dickson. SANATORIUM—Reuben A. McBrayer; Sanford Webb Thompson Jr.

Hyde County

FAIRFIELD—Thomas Preston Burrus; Thos. A. Mann.

Iredell County

MOORESVILLE—Pinkney Jones Chester. STATESVILLE—R. A. Campbell; James Wagner Davis; John Calvin Dye; Colte Long Sherrill. SWEET HOME—Edward Steptoe King.

Jackson County

SYLVA—Charles Z. Candler; Grover Wilkes.

Johnston County

KENLY—George Stephenson Coleman; Grover Barney Woodward. PRINCETON—Oscar Eason. SELMA—William Edward Wilmerding. SMITHFIELD—Thel Hooks.

Jones County

MAYSVILLE—Colin Shaw.

Lee County

JONESBORO—Evander McNair McIver. SANFORD—Charles L. Scott.

Lenoir County

KINGSTON—Mercer Parrott; Vance Peery. LA GRANGE—George L. Pritchard.

Macon County

HIGHLANDS—Geo. S. McPherson.
HIGHLANDS—George Sturtevant McPherson.

Madison County

MARS HILL—Oliver Linwood Stringfield.
SPRING CREEK—Allen G. Thurman Hipps.

Martin County

OAK CITY—Wooster Hassell House. WILLIAMSTON—Roderick Mark Bule; Hugh Brantley York.

McDowell County

OLD FORT—Donald Munro McIntosh.

Mecklenburg County

CHARLOTTE—James Ramsey Alexander; William Allan; Dewitt Ray Austin; James A. Bangle; Eli C. Boyette; Addison George Brenizer; Vanderbilt Brown.

Joseph H. Caldwell; Thomas Craven; John Donnelly; Albert Durham; Lawrence Merrill Fetner; Robert Miller Gallant; Marcus Calvin Houser; Leighton Watson Hovis; Baxter R. Hunter; Myers Hunter; Robert Frederick Leinbach.

John Wilson MacConnell; James Pleasant Matheson; Hamilton Witherspoon McKay; Robert Alexander Moore.

Samuel Albertus Rhyne; John Kirkland Ross; James W. Squires; Maurice Lyndon Townsend; William E. Wishart.

MATTHEWS—John William Law Orr.
CHARLOTTE—Parks McCombs King; Isaac William McLean.

Mitchell County

BAKERSVILLE—Arthur David Gouge.

Montgomery County

STAR—Ernest Lee Dameron. TROY—Charles Wallace Armstrong; Charles Daligny.

Moore County

CARTHAGE—Charles Talmadge Grier.

Nash County

BAILY—Malthus Reaumer Freeman. BATTLEBORO—Arthur Wood Deans. NASHVILLE—John A. Winstead.

New Hanover County

WILMINGTON—Ernest Southerland Bullock; Herbert Augustus Codington; Andrew Howell Harriss; Joseph Ward Hooper; John Walcott Kay; John Bunyan LeGwin.

James Farish Robertson; William Thomas Ruark; Egbert Theophilus Scott; John Thames; John Eugene Wine.

Northampton County

GARYSBURG—Carl Putnam Parker. POTECASI—Paul G. Parker. RICH SQUARE—Joseph Clinton Vaughan. WOODLAND—Walter Raleigh Parker.

Orange County

CHAPEL HILL—Eric Alonzo Abernethy; Louis Harward Webb. HILLSBORO—*Robinette Burns Hayes.*

Pamlico County

KANNAPOLIS—Randolph Edwin Watts.

Pasquotank County

ELIZABETH CITY—Claude Williams. WEEKSVILLE—Richard Boyd Davis.

Pender County

ATKINSON—John Thomas Hoggard.

Perquimans County

HERTFORD—Thomas Shelton McMullan.

Person County

ROXBORO—Samuel S. Montague; Benjamin Adams Thaxton.

Pitt County

AYDEN—George Grady Dixon. BETHEL—Cecil Garrenton. FARMVILLE—Herbert Pennell Mosely. GREENVILLE—Milton Thomas Edgerton; Cicero Jasper Ellen; James Cannon Greene; Charles O'Hagan Laughinhouse; Karl B. Pace.

Polk County

TRON—Marion Cherigny Palmer.

Randolph County

RANDLEMAN—Henry Walter Tidmarsh.

Richmond County

HAMLET—Wm. Moncure Jr. POWELTON—Neill Graham Nicholson Jr. ROCKINGHAM—Frank Bernard Garrett; John H. Quick.

Robeson County

LUMBERTON—Russell S. Beam. RED SPRINGS—William P. McKay. ST. PAULS—John Fredk. Nash; Claude Terrel Poole.

Rockingham County

REIDSVILLE—Harvey Robinson. SPRAY—Samuel Walker Hurdle; Andrew F. Tuttle

Rowan County

GOLDSBORO—Paul C. Carter. ROCKWELL—Glenn W. Choate. SALISBURY—Jacob Henry Rozelle; Carl M. Van Poole; Chalmers Van Poole.

Rutherford County

CAROLEEN—William Ernest Brackett. RUTHERFORDTON—Henry Norris; William Marvin Scruggs.

Sampson County

CLINTON—Bruce Fowler Butler; Eugene Ramsey Hardin; John Kerr Jr. GARLAND—William Henry Sloan. INGOLD—David B. Sloan. KERR—Grover Cleveland Beard.

Scotland County

GIBSON—Everett A. Livingston. LAURINBURG—Nicholas Boddie Cannady.

Stanly County

ALBEMARLE—Jasper Neill Anderson; Lucius Victor Dunlap; Charles E. Lyday, Levin Freeland Mayruder; Floyd Caldwell Shugart. NORWOOD—Thomas A. Hathcock.

Stokes County

GERMANTON—Paul Augustus Petree. PINNACLE—Bernard Holman. WALNUT COVE—Beverly Nicholas Jones.

Surry County

ARARAT—Alex Franklin Jones. MT. AIRY—Edward Clayton Ashby; Darius Cleveland Absher.

Transylvania County

BREVARD—Thomas Johnson Summey.

Union County

MONROE—Robert Lee Payne. WAXHAW—Lemuel Edwin Guin. WINGATE—Robert Jones Lovill; Edward Jerome Williams.

Vance County

HENDERSON—William Henry Bryant; Numa Haden Crews; Edwin F. Fenner; Leland Carson McIntosh; Thomas Clinton Tinsley. KITTRELL—Frederick Overton Swindell.

Wake County

CARY—Carlyle Edwards. HOLLY SPRINGS—Wiley Simon Cozart Jr. RALEIGH—Carl Wendell Bell; Alton Cook Campbell; Kelso Adair Carroll; Amzi Jefferson Ellington; Thomas Woodly Haywood; Wilbur Gibson Jenkins; Robert S. McGeachy; John Sasser McKee; Alfred Mordecai; Robert Primrose Noble; Arthur Sylbert Pendleton; Ivan M. Proctor; Hickman Ray; John E. Ray; Hubert A. Royster; Ralph S. Stevens; Hugh Alexander Thompson; Frank Johnson Thornton; Henry Gray Turner; Louis Nelson West; Thaddeus Earl Wilkerson. WAKE FOREST—Luther T. Buchanan Jr.; John Brewer Powers. WENDELL—John L. Moore. ZEBULON—Chas. Ely Flowers.
RALEIGH—Lemuel Thackara Delany.
WAKE FORREST—Wm. T. Carstarphen.

Wayne County

GOLDSBORO—Ralph L. Daniels; Marshall H. Hood; Richard Spicer. MOUNT OLIVE—George Blythe Morris. SAULSTON—Hector McLean Person.

Wilson County

WILSON—James Cornelius Braswell; Elijah Thomas Dickerson; Michael Saliba; Ernest Lee Strickland; Charles LeRoy Swindell.

Yadkin County

EAST BEND—John Thomas Benbow.

NORTH DAKOTA STATE MEDICAL ASSOCIATION

Officers 1917-18

G. M. Williamson, President	Grand Forks
Edgar A. Pray, First Vice President	Valley City
W. P. Baldwin, Second Vice President	Casselton
Fred Ewing, Third Vice President	Kenmare
H. J. Rowe, Secretary	Casselton
W. F. Sihler, Treasurer	Devils Lake

Councilor Districts and Officers

First District.—Cass and Ransom counties. Paul Sorkness, Councilor, Fargo.

Second District.—Benson, Pierce, Ramsey, Rolette and Towner Counties. W. D. Jones, Councilor, Devils Lake.

Third District.—Cavalier, Grand Forks, Nelson and Pembina counties. J. E. Countryman, Councilor, Grafton.

Fourth District.—Burke, Pierce (part), Ward and Williams counties. A. S. Nicholson, Councilor, Williston.

Fifth District.—Barnes and Griggs counties. W. P. Baldwin, Councilor, Casselton.

Sixth District.—Adams, Burleigh, Emmons, Hettinger, McLean, Mercer, Morton and Stark counties. F. R. Smyth, Councilor, Bismarck.

Seventh District.—Stutsman County. G. Golseth, Councilor, Jamestown.

Eighth District.—Dickey, LaMoure, Richland and Sargent counties. L. B. Green, Councilor, Edgeley.

Ninth District.—Eddy, Foster and Wells counties. Chas. MacLachlan, Councilor, New Rockford.

Tenth District.—Traill and Steele counties. James Grassick, Councilor, Grand Forks.

1. County recently organized; area included with that of other counties.

HONOR ROLL

Adams County

HETTINGER—*Carl Voss.*

Barnes County

FINGAL—Alexander Campbell MacDonald. VALLEY CITY—Charles E. Hunt; Joseph Williams Livingstone; Alexander W. MacDonald.

Benson County

ESMOND—Louis Belfair Derdiger. OBERON—Chas. Ray Tompkins.

Bottineau County

OMEMEE—William Ginsberg.

Bowman County

BOWMAN—Mark Mizener.

Burleigh County

BISMARCK—Julius O. Arnson; John Alfred Halgren; Hugo Mella; Eric Peer *Quain.* *REGAN*—Philip G. Reedy.

Cass County

ARTHUR—Thomas Roy Campbell. CASTLETON—William P. Baldwin. FARGO—James Prentiss Aylen; Frederick Harris Bailey; Walter Darrow Bayard; Geo. Albert Carpenter; Frank Irons Darrow; Harry John Fortin; James Francis Hanna; Axel Oftedal; Martin Philip Rindlaub. HUNTER—Herbert M. Knudtson.

Cavalier County

LANGDON—Judd Harris Kirkham. MUNICH—Edward Rudolph Lindner.

Divide County

NOONAN—*Joseph Allen* Smith.

Emmons County

HAZELTON—George Monteith.

Foster County

CARRINGTON—Edwin Lincoln Goss; John Ross MacKenzie.

Golden Valley County

BEACH—Alexander *Blake* McNab.

Grand Forks County

GRAND FORKS—Wilhelm S. Anderson; Theodore Bratrud; Robert Donald Campbell; Henry Herbert Healy; *John* Arnason Johnson; Olaf Kittelson; Orville Newton Meland; Arthur Peake.

Hettinger County

MOTT—Fred Eli Redman; *Fred T. Rucker.*

Kidder County

DAWSON—Roscoe Conkling Pryse.

La Moure County

KULM—Jacob Frederick Brenckle. LA MOURE—Martin Daniel Westle VERONA—Herbert Bertram Wentz.

McIntosh County

ASHLEY—Edwin Herman Maercklein.

McLean County

MERCER—Ralph Deming.

Mercer County

HAZEN—Leslie Guy Eastman. STANTON—Cecil Clifford Smith.

Morton County

MANDAN—Bernard Smith *Nickerson.*

Mountrail County

PARSHALL—Guy Samuel *Frogner.* PLAZA—Gustave Leander Rude STANLEY—*Frank Otis* Joseph Brigham. WHITE EARTH—Edward Kennedy.

Pembina County

CAVALIER—Charles Augustus Short.

Pierce County

RUGBY—James Edward Cramond. *WESTBY*—Jesse *Lot* Norris.

Ramsey County

BROCKET—John Aldren Dean Engesather. DEVILS LAKE—Ca Fisher; *George* Vere Jamieson; William F. Sihler.

Ransom County

ENDERLIN—Arley John Ostrander. LISBON—Thomas C. Patterso Ernest E. Wands.

Renville County

GLENBURN—Knute Otto Knudson. SHERWOOD—John Percy Greave

Richland County

HANKINSON—Dennis Edward Ryan. WYNDMERE—*Kenneth* Wa Wilder.

Rollette County

ROLLA—Bernard D. Verret.

Sargent County

COGSWELL—Charles E. Howard; *Howard Lee Saylor.*

Sioux County

SOLEN—Paul Frederick Rice.

Stark County

DICKINSON—William *H. Long;* Aloysius Patrick Nachtway; Victo *Hugo* Stickney.

Steele County

FINLEY—Andrew John Heimark.

Stutsman County

JAMESTOWN—Thomas Lloyd DePuy; William Albert Gerrish. MONT*PELIER*—Joseph Henry Plant.

Towner County

BISBEE—Axel Waldemar Swenson. EGELAND—Wayne Paul O'Brien

Walsh County

GRAFTON—John Edgar Countryman; Cyril John Glaspel. PARK RIVER—Clarence Wm. Robertson; Frank Elmer Weed.

Ward County

BERTHOLD—Samuel Joseph Hillis. KENMARE—Neil McLean. *MINOT*—J. Charles Jackman; Alexander J. McCannel; John Wesley Newlove; John Robert Pence; Frank E. Wheelon.

Wells County

SYKESTON—Ellis Frank Swarthout.

Williams County

EPPING—Dickenson Ober Wheelock. TIOGO—Simon Benhard Oliver. WILLISTON—Carlos Selby Jones; Hilmar Thorer Skovholt; Thomas Jefferson Strong.

OHIO STATE MEDICAL SOCIETY

Officers 1917-18

E. O. Smith, President	Cincinnati
J. F. Baldwin, President-Elect	Columbu

3. Includes Tulsa, population 32,507; physicians 120 [M.R.C. 11].

Canadian County

EL RENO—Fred H. Clark; Philip Frickelton Herod; Ontie Horenden; Daniel Miller Moore.

Carter County

ARDMORE—David Albertus Gregory; George Bennett Scott. HEALDTON—Charles Crawson Sims.

Cherokee County

PARK HILL—John Frank Duckworth. TAHLEQUAH—Houston E Fite; Charles Arthur Peterson; Joseph Martin *Thompson.*

Choctaw County

HUGO—Edgar Allen Johnson; Henry Whitfield Malers. SOPER—Thomas Anderson Hartgraves.

Cleveland County

LEXINGTON—Clarence Edward Northcutt; John Lestrange Bock; Robert Edward Lee Thacker. NORMAN—Thomas Nadison Boyd; *John Le*[illegible] Day; James Jackson Gable; Stephen H. Graham; Reuben Morgan Hargrove; Richard Emmett Thacker.

Coal County

COALGATE—Finis Ewing Rushing. TUPELO—William Thomas Blount.

Comanche County

CHATTANOOGA—William Brown Harned; George E. Kerr. FAXON—Chonner Polk Chumley. FT. SILL—William P. Lipscomb. LAWTON—George Stanley Barber; Jackson Brashear; Joseph T. Edward; James Garfield Janney; James Lang Lewis; Louis A. Milne; Cecil Elbert Tolle.

Cotton County

TEMPLE—Charles Watts Alexander.

Craig County

VINITA—Louis Bagby; Powell Lambert Hays; Will Wilson Jackson; Walter Roscoe Marks; Robert Lee Mitchell.

Creek County

BRISTOW—Joseph J. Nabhan. DRUMRIGHT—Charles Dallas Blachley; Matthew Karasek; William Penn Sims; Orange Walter Starr. KELLYVILLE—Isaac Walter Rogers. MILFAY—Levi P. Murray. SAPULPA—Erskine D. Johnson.

Custer County

CLINTON—Monte Cristo Comer. THOMAS—William Joseph Omer.

Dewey County

OAKWOOD—Esley Elwood Lawson. VICI—Charles Edward Houser.

Ellis County

ARNETT—Albert Alonzo Stoll. FARGO—Fred Lindley Patterson.

Garfield County

ENID—Wallace Andrew Aitkin; Lyman Lyndon Bunker; Frank Glenn Francisco; Charles Edward Thompson. HUNTER—*Waldo* Bee M. B. Newell. LAHOMA—Harry Fitzgerrell Vandiver.

Garvin County

LINDSAY—Samuel Warren Wilson. PAULS VALLEY—Calvin Luther Johnson. STRATFORD—Marion McDowell Webster. WYNNEWOOD—Robert Lee Baker.

Grady County

BRADLEY—William R. Barry. CHICKASHA—Harry Clifford Antle; Lewis Edgar Emanuel. VERDEN—George Madison McVey; Woodward Roberts Mitchell.

Grant County

BALKO—William Stout. WAKITA—William Emery Harrington.

Greer County

GRANITE—Thomas Junior Nunnery. MANGUM—Rufus Leroy Holt; *Frank Harrison McGregor.*

Harmon County

GOULD—William G. Husband. LOUIS—Oscar Johnston Street.

Harper County

CHARLESTON—Elmer Ethelbert Heady. ROSTON—Hardin Walker.

Haskell County

ENTERPRISE—Jarrett Jeffrey Billington. KINTA—Jesse Ray Waltrip. STIGLER—Frank A. Fannin; Samuel Erskin Mitchell; Harry James Sims.

Hughes County

DUSTIN—Jesse William Smith. LAMAR—Georgia M. Combest. WETUMKA—Casper A. Hicks.

Jackson County

ALTUS—James Jackson Caviness; Raymond H. Fox; Davy Lewis Garrett; Samuel Houston Landrum. BLAIR—Herman August Laforce.

Jefferson County

HASTINGS—Henry DeWitt Shankle. RYAN—Lisby Lucius Wade.

Johnston County

CONNERVILLE—William J. Rogers.

Kay County

BLACKWELL—Alonzo Pit Gearhart; James Clinton Hawkins. NEWKIRK—Abraham Lincoln Hazen. TONAWA—Ethan Estey Waggoner.

Kingfisher County

CASHION—James Robert Bost; Francis Ray First. KINGFISHER—John Winston Pendleton.

Kiowa County

COOPERTON—Paul Raymond Siberts [illegible] m Watkins. [illegible] Clay I [illegible] Henry Calvin [illegible] VIEW— [illegible] Rea.

Latimer County

WILBURTON—Garnett A. Kilpatrick.

Le Flore County

HOWE—Arthur Guy Hunt. POTEAU—Novel Walter Campbell. SPIRO—George Ewin Hartshorne. TALHINA—Robert Melvin Shepard.

Lincoln County

CHANDLER—James Elston Adams; Walter Griswold Bisbee. DAVENPORT—Ulus Edgar Nickell. KENDRICK—Joseph Mitchell Hancock. SPARKS—Frederick C. Brown.

Logan County

GUTHRIE—William Ward Rucks; Thomas H. Wright. MARSHALL—Henry Charles Tyler Richmond. WIRT—Thomas Maxwell Toler.
GUTHRIE—Robert Elliott Long.

Love County

MARIETTA—Alfred Edwin Martin. THACKERVILLE—William Wesley Lightfoot.

Marshall County

KINGSTON—Orange Elbert Welborn. WOODVILLE—James Allen Rutledge.

Mayes County

PRYOR—Joseph William Garrett; Carl Puckett; George Washington Tilly; William Jerry Whitaker.

McClain County

WASHINGTON—Ernest Ezra Nunnery.

McCurtain County

BROKEN BOW—Clarence Randle McDonald. OAK HILL—William G. Baird.

McIntosh County

CHECOTAH—Alexander Boyd Montgomery. EUFAULA—Daniel Erastus Little; John Norris Shaunty.

Murray County

SULPHUR—Howson Clark Bailey; William Medwin Tucker.

Muskogee County

MUSKOGEE—Benjamin Henton Brown; Albert Nila Earnest; William Otto Fischer; William P. Fite; James Grady Harris; Charles William Heltzman; Roland Howlin Holcombe; Edward David Morrison; Robert William Motley, Pleasant Pomeroy Nesbitt; Joseph Glass Noble; Joseph Hoy Sanford; Charles Ersey Smith; Joseph Harry Stolper; Claude A. Thompson; Floyd Edward Waterfield. WEBBERS FALLS—Eugle A. Campbell.

Noble County

BILLINGS—James Marshman Cannon; Thomas Franklin Renfrow. REDROCK—Charles Percy Murphy.

Nowata County

ALLUWE—John Gordon Thomas. NOWATA—Russell Lenoir Kurtz.

Okfuskee County

OKEMAH—Jesse Monroe Pemberton.

Oklahoma County

EDMOND—Samuel Newton Stone. OKLAHOMA CITY—Frank Marion Bailey; Archie Bee, Abraham Lincoln Blesh; Floyd J. Bolend; Rex George Bolend; Charles Arthur Brake; Frederick Albert Cochran Jr.

Albert Ewing Davenport; Francis Asbury DeMand; Robert Berry Gibson; Austin Lee Guthrie; James Worrall Henry; Albert Clifford Hirshfeld; Merle Quest Howard; Robert Mayburn Howard; George Hunter.

Lewis E. Inman; Benjamin George Jones; Wann Langston; Thomas LeRoy Lauderdale; Clarence Edward Lee; Ross David Long.

John Charles Mahr; Aelphar A. Marstellar; George Davidson McLean; John Z. Mraz; Littleton Alexander Newton; David Dare Paulus.

Howard L. Reed; Marion Mansfield Roland; Lloyd M Sackett; Fenton Mercer Sanger; Herbert V. L. Sapper; Frank Bruner Sorgatz; Marvin Elroy Stout; Simon E. Strader; Elijah Stover Sullivan; Duke William Vincent; Roy Abner Webb; Curt Otto von Wedel; Willis Kelly West; Lee Roy Wilhite; Earl Leroy Yeakel; Andrew M. Young; Antonio Debord Young.

Okmulgee County

COALTON—Clarence Lovejoy Wellman. HENRYETTA—Harry A. Briggs; John Lee Riley. MORRIS—James Otto Walls. OKMULGEE—Virgil Berry; Charles Morris Ming; Harvey Ollis Randel; Robert Leland Westover.

Osage County

AVANT—Isaac F. Clark. GRAINOLA—Edward Louis Miller.

Ottawa County

MIAMI—Guy Peery McNaughton. TAR RIVER—Elmer Franklin Garlington.

Pawnee County

CLEVELAND—Harman Brewer McFarland; Elam Theodore Robinson. HALLETT—Robert Ellee Calhoun. RALSTON—Earl Duwain McBride.

Payne County

STILLWATER—James Henry Mallory; Harry McQuown.

Pittsburg County

[illegible] Hope Foster. [illegible] Gardner. [illegible] Sales Riley. [illegible] Baker. [illegible] B. Bellinger; L [illegible], Leonard [illegible] Jefferson Palmer.

1. County recently organized; area included with that of other counties.
2. Includes Portland, population 308,399; physicians 500 [M.R.C. 90].

HONOR ROLL

Baker County

BAKER—Clifton Leonard Blakely; *Thomas Joseph Higgins*; Albert William Tiedemann. HAINES—Roger Biswell.

Benton County

CORVALLIS—Harry J. Anderson; Emile Casper Joseph.

Clackamas County

[illegible] Ray Taylor. OREGON CITY—Walter East Mount; Orel Alvin Welsh. OSWEGO—Eugene [illegible] NVILLE—Willis Dole Butler.

Clatsop County

ASTORIA—Arthur Alexander Finch; Alfred E. Kinney; Eldred B. Waffle. SEASIDE—Lance E. Briscoe; Frank Van Doren.

Columbia County

CLATSKANIE—James Leonidas Wooden.

Coos County

BANDON—Smith J. Mann. COQUILLE—George Earl Low. MARSHFIELD—Everett Mingus; Howard Messenger Shaw; Edwin Ephraim

Crook County

PRINEVILLE—John Henry Rosenberg.

Curry County

GOLD BEACH—Carl William Robbins.

Douglas County

RIDDLE—*Arthur* Jesse *Fawcett*. ROSEBURG—*George E.* Houck; *Frank H. S. Vincil*; Charles B. Wade. SUTHERLIN—Orra Edgar Patterson.

Grant County

CANYON CITY—Leo W. Chilton. LONG CREEK—*Philip L.* Newmyer.

Hood River County

HOOD RIVER—Vestal Raul Abraham; John Wesley Sifton; Justin Miner Waugh.

Jackson County

ASHLAND—Arthur William Boslough; S. Gordon MacCracken. GOLD HILL—*William Parmer Chisholm*. MEDFORD—Robert Wellington Clancy; Clark Edw. Saunders; Eberle Randolph Seely.

Jefferson County

WARMSPRING—Clarence Dale Fulkerson.

Josephine County

GRANTS PASS—Julian Philip Johnson; Frederick David Stricker; Jesse P. Truax.

Klamath County

KLAMATH FALLS—Riden Roy Hamilton.

Lake County

LAKEVIEW—Ernest Day Everett; Mearle C. Fox. *NEW PINE CREEK*—John Lucius *Garner*.

Lane County

COTTAGE GROVE—Charles E. Frost. EUGENE—George Ernest Darrow; Reuben Harrison Fields; Wilbur Thomas Gullon; John Eberle Kuykendall; *Thomas Horace* Miller; Sam Clarence Standard Amos O. Waller; Edw. L. Zimmerman. JUNCTION CITY—Merle George Howard; *Daniel Patterson Love. MABEL*—C. Harold Palmer . SPRINGFIELD—Joseph Randolph Barr; *Eugene Kester*; William Howard Pollard.

EUGENE—Benjamin Franklin Scaicfe.

Lincoln County

NEWPORT—Walter Cayley Belt.

Linn County

LEBANON—Joll C. Booth. SCIO—Will Hale Potter.

Malheur County

VALE—Carl Jackson Bartlett. *JUNTURA*—William Elias Hedges.

ONTARIO—Jacob Prinzing.

Marion County

JEFFERSON—Joseph Olin Van Winkle. MOUNT ANGEL—James Ellsworth Webb. *SALEM—Charles Elmer Bates*; Roy Dean Byrd; Harry Elwin Clay; Julius Herman Garnjobst; Lloyd H. Mott; Dick Raymond Ross; *William Carlton Smith. SILVERTON—Floyd D. Lewis; Henry* William Steelhammer. WOODBURN—William W. Kettle; Victor L. Rocho.

Morrow County

HARDMAN—George Garber Gaunt. HEPPNER—Harold T. Allison.

Multnomah County

BRIDAL VEIL—*Sam Frank Le Fevre. PORTLAND*—John George Abele; *Elmer Everett Anderson*; Robert Louis Benson; Nathan *Morris Benyas; Linford Shepheard Besson; Charles Billington; Varillas C.* Birney; Arther Trew Blachly; Charles Delos Bodine; *Amos* Watt Botkin; Isadore C. Brill; *Lloyd Wesley Brooke*.

Roscoe William Cahill; William Maxwell Campbell; T. Homer Coffen; Isadore Henry Cramer; *Ernest* Charles Dalton; Ferdinand H. Dammasch; *Richard Benjamin Dillehunt; Chester Arthur Downs*.

Ralph Albert Fenton; Eric Julian Gambee; Robert St. Clair Graffis; Daniel Grant; Herbert Merton Greene; Albert Allen Grossman; Fred Gullette; Frank Cleveland Hart; Ernest D. Hitchcock; John Adam Hughes; Garrett Lee Hynson.

Richard F. James; Marion Jacobs Jones; Thomas Martin Joyce; Joseph Edward Kane; William Sidney Knox.

Fred Adcok Lieuallen; *Kenneth Alexander J.* MacKenzie; James Lorne Manion; William Orville Manion; Marius B. Marcellus; Charles Rafferty McColl; Clarence Joseph McCusker; *Frank Raymond* Menne; *Percy F.* McMurdo; Dwight F. Miller; Harry B. Moore; Karl Peterson Moran; Earl Vincent Morrow; Edwin Woodbridge Morse.

Benjamin L. Norden; Charles Cowan Osborn; Dorwin L. Palmer; Joseph August Pargon; Ray Emmett Pomeroy.

David Nathaniel Roberg; Alpha E. Rockey; *Paul Rockey*; *Horace* Louis Rosenberg; Arthur Samuel Rosenfeld.

Spiro Sargenitch; Eweldas Kallistas Scott; William George Scott; Charles Edwin Sears; Lawrence Selling; John James Sellwood; William Albert Shea; Robert Archie Sherwood; Harry Everett Shoot; William Henry Skene; Clarence U. Snider; Ernst August Sommer; John Archibald Stewart; William Edgar Stewart; George Burnside Story; Ernest Hamilton Streit; John Guy Strohm; Karl Joaum Swenson.

Archie Clifford Van Cleve; William Henry Vose; Benjamin Newton Wade; Joseph Robbins Wetherbee; Calvin Stuart White; George Shattuck Whiteside; Otis Buckminster Wight; George Flanders Wilson; Louis Jacob *Wolf*; Joseph Frederick Wood; Robert Clark Yenney; Edward Frank Ziegelman.

PORTLAND—Ernest Nathaniel Crockett; William Boyd Hamilton; William Charles Munly; Leon E. Story; Richard Howells Wellington.

Polk County

DALLAS—Lenthal A. Bollman. FALLS CITY—Glenn Edw. Prime. INDEPENDENCE—*Chas.* Francis *Cropp*.

Umatilla County

HERMISTON—Clyde Otis Wainscott. PENDLETON—James Archibald Best; Hillis Hall Hattery; James D. Plamondon. PILOT ROCK—Lansford Monroe Spalding. WESTON—Charles Henry Smith; *Henry Zophar* Tharp.

Union County

COVE—Arthur Clifford McCown. HOT LAKE—Frank Earnest Butler. IMBLER—Carl Sinclair *Moore*. LA GRANDE—Harry Matthew Boury; Frank Leslie Ralston; Herbert Lyman Underwood; George Rudolph Vehrs

Wasco County

MAUPIN—John Lewis Elwood. THE DALLES—Thompson Coberth.

Washington County

BUXTON—Prince C. Page. FOREST GROVE—Charles Edwin Hawke. ORENCO—John Bell Dinsmore.

Wheeler County

FOSSIL—Hugh Samuel McKenzie.

Yamhill County

McMINNVILLE—Edgar Hayes Brown; Charles L. Williams. NEWBERG—Harris Augustus Littlefield; John Silas Rankin. YAMHILL—Howard Ernest Carruth; Roy Bennett Craver.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Officers 1917-18

Walter F. Donaldson, President..............................Pittsburgh
B. Franklin Royer, 2d Vice President........................Harrisburg
David N. Dennis, 3d Vice President.................................Erie
Walter J. Leaman, 4th Vice President....................Leaman Place
Cyrus Lee Stevens, Secretary......................................Athens
Christian B. Longnecker, Asst. Secretary..................Philadelphia
Geo. W. Wagoner, *Treasurer*.....................................Johnstown

Councilor Districts and Officers

Horatio W. Gass, Chairman, Sunburg.

First District.—1st and 3d Censorial Districts.—Berks, Chester, Delaware, Montgomery, Philadelphia and Schuylkill counties. Ira G. Shoemaker, Councilor, Reading.

Second District.—4th and 5th Censorial Districts.—Adams, Cumberland, Dauphin, Franklin, Fulton, Lancaster, Lebanon and York counties. Frank G. Hartman, Councilor, Lancaster.

Third District.—2d and 18th Censorial Districts.—Bucks, Carbon, Lackawanna, Lehigh, Luzerne, Monroe, Northampton, Pike and Wayne counties. Harry W. Albertson, Councilor, Scranton.

Fourth District.—6th and 7th Censorial Districts.—Columbia, Huntington, Juniata, Mifflin, Montour, Northumberland, Perry and Snyder counties. Horatio W. Gass, Councilor, Sunbury.

Fifth District.—7th and 15th Censorial Districts.—Bedford, Blair, Cambria, Center, Clearfield, Fayette, Somerset and Westmoreland counties. Spencer M. Free, Councilor, DuBois.

Sixth District.—14th and 16th Censorial Districts.—Bradford, Clinton, Lycoming, Sullivan, Susquehanna, Tioga, Union and Wyoming counties. Donald Guthrie, Councilor, Sayre.

Seventh District.—8th and 9th Censorial Districts.—Allegheny, Beaver, Greene, Lawrence, Mercer and Washington counties. Irwin J. Moyer, Councilor, Pittsburgh.

Eighth District.—10th and 11th Censorial Districts.—*Cameron*, Crawford, Elk, Erie, McKean, Potter and Warren counties. *James Johnston, Councilor, Bradford.*

Ninth District.—12th and 13th Censorial Districts.—Armstrong, Butler, *Clarion, Forest*, Indiana, Jefferson and Venango counties. J. B. F. Wyant, *Councilor*, Kittanning.

CLINTON—Leslie St. Clair Hays; Theodore James Peake. CROSS HILL—George Fred Klugh; Claude Benjamin Mills.

Lee County

BISHOPVILLE—Lacy Wood Corbett; Harvey McNair McLure.

Lexington County

BATESBURG—Joseph Benjamin Edwards. LEESVILLE—*Carl Lafayette* Able.

Marion County

MARION—Carroll Sumner Howell; George Madison Truluck. MULLINS—Alex. Brailsford Jr. NICHOLS—Claudius Franklin Bullock.

Marlboro County

BENNETTSVILLE—Lawrence Randolph Kirkpatrick; *Daniel Deronda* Strauss.

McCormick County

CLARKS HILL—Ben Tillman Sharpton.

Newberry County

NEWBERRY—William *Ernest Bickley*; *Frank* Duano Mower; John Bachman Setzler. WHITMIRE—Thomson Butler Woods.

Oconee County

CLEMSON COLLEGE—Thomas *Craig Redfern*. NEWRY—William Clinton Marett. WALHALLA—Bayliss Frank Sloan; John David Verner Jr.

Orangeburg County

EUTAWVILLE—Rembert James Coner. NEESES—Grover Cleveland Bolin. ORANGEBURG—[illegible]tgomery; Henry P. Moore; Henry [illegible] SPRINGFIELD—[illegible] D. Busbee.

Pickens County

EASLEY—James Carl Pepper; John Wallace. *LIBERTY*—Clark Wales Smith. *PICKENS*—Lewis Franklin Robinson.

Richland County

COLUMBIA—[illegible] Baggot; Clarendon Witherspoon *Barron*; Ge[illegible] Boling; Francis A. Coward; Robert Blakely Du[illegible] Cyrus Galloway; Emmet Merrick Harrison; James A. Hayne; George Kaigler Nelson; Lindsay Peters; James E. Poore; Floyd Dwight Rodgers; Isadore Schayer; John La Bruce Ward; Carl Alexander West; Samuel Edward Wheeler; Marion Hay Wyman; Edward C. L. Adams.

Saluda County

MONETTA—Boldridge Edward Kneece. *RIDGE SPRING*—Laomi Josiah Smith.

Spartanburg County

CAMPOBELLO—Charner LeRoy Stevens. FAIRMONT—Thurman Gregory Wright. SPARTANBURG—Walter Brackett Lancaster; Cecil *Rigby*; William O. Wrightson.

Sumter County

HAGOOD—[illegible]lichampe Moore; Frank Butler Sanders. [illegible] W. Corbett. OSWEGO—Benjamin Franklin [illegible] Hamilton Burgess; William Sydney Burgess; Carl Belden Epps; William W. Felder.

Union County

BUFFALO—Fitzhugh Prothero Salley. LOCKHART—William Stewart McMurray. SANTUCK—James Thomas Jeter. UNION—Theodore Maddox.

Williamsburg County

KINGSTREE—Clarence David Jacobs. NESMITH—Allston Moore Willcox. OUTLAND—Oscar Lucas Bruorton.

York County

CLOVER—James W. Campbell; Ebenzer Widman Pressly. McCONNELLSVILLE—John Walker Moore. ROCK HILL—William Robert Blackmon; Robert Hope Crawford. SHARON—James Luther Blair. YORK—Phillip Williams Hunter.

SOUTH DAKOTA STATE MEDICAL ASSOCIATION

Officers 1917-18

H. J. G Koobs, President ....Scotland
D. L. Scanlon, First Vice President.... ....Volga
Harry T Kenney, Second Vice President.........................Pierre
R. D. Alway, Secretary-Treasurer...............................Aberdeen

Councilor Districts and Officers

Wm. Edwards, President, Bowdle; Harry T. Kenney, Secretary, Pierre.

First (Aberdeen) District.—Roberts, Marshall, Day, Brown, Spink, Faulk, Edmonds, McPherson, Campbell, Walworth, Potter, Dewey, Grant (north half), and Corson counties. Wm. Edwards, Councilor, Bowdle.

Second (Watertown) District.—Codington, Grant (south half), part of Deuel, Hamlin (north half) and Clark counties. L. G. Hill, Councilor, Sioux Falls

Third (Brookings) District.—Brookings, Kingsbury, Lake (north half), Miner (north half) and Beadle counties. N. K. Hopkins, Councilor, Arlington.

Fourth (Pierre) District.—Hand, Hyde, Hughes, Sully, Buffalo, Stanley and Tiebach counties H T Kenney, Councilor, Pierre.

Sixth (Mitchell) District.—Davison, Hanson, McCook (west half), Aurora, Brule, Lyman, part of Hutchinson, part of Turner, part of Sanborn and Jerauld counties. Fred Treon, Councilor, Chamberlain.

Seventh (Sioux Falls) District.—Minnehaha, McCook (east half), Lincoln, part of Moody and part of Turner counties. G. G. Cottam, Councilor, Sioux Falls

Eighth (Yankton) District.—Yankton, Clay, Union, Bon Homme, part of Turner, Douglas, Charles Mix, part of Hutchinson, Gregory, Tripp and Todd counties James Roane, Councilor, Yankton.

Ninth (Black Hills) District.—Butte, Lawrence, Meade, Fall River, Bennett and Pennington counties. F. E. Ashcroft, Councilor, Deadwood.

Tenth District.—H R. Kenaston, Councilor, Bonesteel.

HONOR ROLL

Aurora County

WHITE LAKE—John Clifford Rogers.

Beadle County

HITCHCOCK—Alvin Perry Scheib. HURON—Tillison James Wood; Oscar Reilly Wright

Bon Homme County

SCOTLAND—Gustav Adolph Landmann; Isaac Wellman Leighton. TYNDALL—Eugene Herbert Boon.

Brookings County

AURORA—Jess W. Foster. BROOKINGS—Roscoe Roby Fisk. BRUCE—George Edward

Brown County

ABERDEEN—William E. Clark; James Harry Vetter. GROTON—John Edward Dunn

Brule County

CHAMBERLAIN—Robert Archie Crawford.

Buffalo County

CROW CREEK—Archie McCallister.

Butte County

BELLE FOURCHE—Alexander Otto Fasser; Oscar William Tulisalo. NISLAND—*Francis Everett Townsend.*

Charles Mix County

DANTE—[illegible] *Bonza*. LAKE ANDES—Charles Seymour [illegible] PLATTE—[illegible] T. Anderson; Cleveland F. Brooks. WAGNER [illegible]

Clay County

VERMILION—John Lawrence Brookman; Iver Stoland.

Codington County

[illegible] William Mullen. HENRY—James Day Edgar. [illegible] Thomas Read. WATERTOWN—William August Parsons.

Davison County

MITCHELL—William Reaves Ball; Edward William Jones.

Day County

WEBSTER—Albert Edward Brown; Mads Johnson Fiksdal.

Douglas County

ARMOUR—Frank Delos Wilson.

Fall River County

HOT SPRINGS—James Acker Mattison.

Grant County

MILBANK—William James Ferguson; Charles Hugo McKenna.

Gregory County..

BURKE—Robert Joseph Quinn.

Hamlin County

CASTLEWOOD—James Harry Crawford.

Hand County

MILLER—Port McWhorter. REE HEIGHTS—James Franklin Paddleford.

---

1. Armstrong, Bennett, Mellette, Shannon, Washabaugh and Washington counties, no physicians reported.

Hanson County

FULTON—George Henry Lowthian.

Harding County

BUFFALO—Daniel Deronda Raber.

Hughes County

PIERRE—Harry Thomas Kenney.

Hutchinson County

PARKSTON—James Gilbert Carney.

Hyde County

HIGHMORE—Glen Vernon Sigler.

Jerauld County

WESSINGTON SPRINGS—Fred Floyd Keene.

Jones County

MURDO—William Moody Hunt.

Kingsbury County

DE SMET—Burt Alvano Dyar. IROQUOIS—Charles Hall Cowgill. OLDHAM—Gebhard Joseph Long Jr.

Lake County

MADISON—Emerson William Goldman.

Lawrence County

DEADWOOD—Felix E. Ashcroft; Thomas W. Moffitt; Maurice Orear Pemberton. LEAD—William Edward Fehliman; Charles Koenigsberger.

Lincoln County

CANTON—Roy F. Sackett.

Marshall County

BRITTON—Frederick Otto Kaps; Dennis William Sullivan.

McCook County

MONTROSE—Lindsay Z. Fletcher.

Meade County

FAITH—Harry Charles Durkee. FT. MEADE—Luke Baker Peck. STURGIS—John Wallace Brackett; John Dosher Brooks.

Minnehaha County

SIOUX FALLS—Thomas Edward Jones; George Alfred Stevens; Thomas Gottfried Thompson.

Moody County

FLANDREAU—Frederick Angier Spafford.

Pennington County

RAPID CITY—William S. Bentley; Henry James Toppin Ince.

Potter County

GETTYSBURG—John Joseph Mertens.

Roberts County

SISSETON—James Everett Dyson; Wallace Isaac Longstreth. WHITE ROCK—Sigfred Engh. WILMOT—Carl Norman Harris.

Sanborn County

WOONSOCKET—Floyd Smelson Kidd.

Spink County

CONDE—Lester Richard Herman. DOLAND—Charles Augustus Williams. REDFIELD—Jacob Gemmill Chichester; Dewey Sutton.

Todd County

ROSEBUD—Leo Louis Elliott.

Tripp County

CARTER—Robert M. Malster; Carl O. Reed. WINNER—Archie Percival Kimball.

Turner County

PARKER—Harley Dore Newby.

Union County

BERESFORD—Arastus Vernon Elliott. ELK POINT—John Henkin; Walter Chafey Moodie.

Yankton County

VOLIN—Irving Miller. YANKTON—Frank Conger Smith; James Augustus Wood.

TENNESSEE STATE MEDICAL SOCIETY

Officers 1917-18

E. T. Newell, President..........Chattanooga
Vice Presidents:—
H. M. Cass..........*Johnson City*
T. G. Pollard..........*Nashville*
W. O. Sullivan..........Newbern
Olen West, Secretary..........Nashville
J. F. Gallagher, Treasurer..........Nashville

Councilor Districts and Officers

First District.—Claiborne, Hancock, Hawkins, Sullivan, Grainger, Greene, Washington, Carter, Unicol, Johnson, Cocke and Sevier counties. C. P. Fox, Councilor, Greenville.

Second District.—Scott, Campbell, Union, Anderson, Roane, Knox, Loudon, Blount, Jefferson and Hamblen counties. S. R. Miller, Councilor, Knoxville.

Third District.—McMinn, Monroe, Polk, Meigs, James, Bradley, Hamilton, Marion, Sequatchie, Bledsoe, Van Buren, White, Warren, Grundy and Franklin counties. J. A. Hardin, Councilor, Sweetwater.

Fourth District.—Rhea, Cumberland, Morgan, Fentres, Putnam, Overton, Pickett, Jackson, Clay, Smith, Macon, Trousdale, Wilson and Sumner counties. Z. J. Shipley, Councilor, Cookesville.

Fifth District.—Lincoln, Marshall, Bedford, Rutherford, Cannon, De Kalb, Coffee and Moore counties. F. B. Reagor, Councilor, Shelbyville.

Sixth District.—Stewart, Montgomery, Robertson, Cheatham and Davidson counties. W. C. Dixon, Councilor, Nashville.

Seventh District.—Houston, Humphries, Dickson, Williamson, Hickman, Maury, Lewis, Lawrence, Giles and Wayne counties. M. A. Beasley, Councilor, Hampshire.

Eighth District.—Carroll, Henderson, Madison, Decatur, Perry, Hardin, Chester, McNairy, Henry and Benton counties. A. B. Dancy, Councilor, Jackson.

Ninth District.—Weakley, Gibson, Obion, Lake, Dyer, Lauderdale, Crockett and Haywood counties. R. W. Griffin, Councilor, Tiptonville.

Tenth District.—Tipton, Shelby, Fayette and Hardeman counties. W. T. Black, Councilor, Memphis.

HONOR ROLL

ALDERSON—Charles Francis Mahood.

Nicholas County

CRAIGSVILLE—Adlai E. Callaghan. RICHWOOD—Walter Fundenberg Leech. SUMMERVILLE—Herbert Clark Kincaid.

Ohio County

ELM GROVE—Reece Means Pedicord. WHEELING—Andrew Linn Coyle; Leech Key Cracraft; William Allen Cracraft Jr.; Lowell Sidney Goin; Eugene Augustus Hildreth; Wm. Eugene Masters; William Hay McLain; Emerson Megrail; Charles Menger Truschel; Ferdinand William Wiehe.

Pendleton County

FRANKLIN—George Price McCoy; UPPER TRACT—Charles Lloyd Moore.

Pleasants County

ST. MARY'S—Homer Willard Grimm.

Pocahontas County

MARLINTON—Norman R. Price. MINNEHAHA SPRINGS—Raymond B. Lockridge.

Preston County

MASONTOWN—Ernest Jacob Wichterman. RAWLESBURG—Foster Carmon Howard. TUNNELTON—Barrick Samuel Rankin.

Putnam County

HURRICANE—Grover Cleveland Roberson.

Raleigh County

AFFINITY—George Fordham. DOROTHY—Benjamin Lewis Pettry. PEMBERTON—Wm. Crocket Corey. RALEIGH—McRay C. Banks.

Randolph County

BEVERLY—William Glen Harper. ELKINS—Hoddie Wilbur Daniels; Charles Henry Laws; Harry Knight Owens. MILL CREEK—Bayard Lee Liggett.

BLOOMFIELD—Waitman W. Orr.

Ritchie County

ELLENBORO—Emmett Addis Corbin. HARRISVILLE—Gordie C. Patton; William Everett Whiteside. PENNSBORO—Latimer Porter Jones.

Roane County

ANIMA—Clyde Harper. SPENCER—Stephen W. Bull; Ross Dodson; John Ewell McQuain; Charles O. Staats. STERLING—Richard Lownsberry Eltings.

Summers County

HINTON—Maurice Clayton James; Harry Clay Lynch. PENCE SPRINGS—George Lewis Pence.

Taylor County

GRAFTON—Emmet Richelieu Bucklew; Dorsey C. Peck.

Tucker County

BEN BUSH—John Smyth Cayce; Charles Wesley Myers.

Tyler County

SISTERSVILLE—Ralph Homer Boice; Frederick Eugene Keller; Robt. Frederick Thaw.

Upshur County

BUCKHANNON—James A. Rusmisel.

Wayne County

WAYNE—John Richard Keesee.

Wetzel County

HUNDRED—Krank M. Kearns. SMITHFIELD—Chas. L. Bates.

Wood County

PARKERSBURG—Oliver D. Barker; Walter Scott Link.

Wyoming County

MULLENS—Byron William Steele.

STATE MEDICAL SOCIETY OF WISCONSIN

Officers 1917-18

G. Windersheim, President.................................Kenosha
Oscar Lotz, First Vice President.................................Milwaukee
T. W. Nazum, Second Vice President.................................Janesville
Carl Doege, Third Vice President.................................Marshfield
Rock Sleyster, Secretary.................................Waupun
S. S. Hall, Treasurer.................................Ripon

Councillor Districts and Officers

First District.—Dodge, Jefferson, Washington and Waukesha counties. M. R. Wilkinson, Councillor, Oconomowoc.

Second District.—Kenosha, Racine and Walworth counties. G. Windesheim, Councillor, Kenosha.

Third District.—Columbia, Dane, Green, Rock, Marquette and Sauk counties. F. T. Nye, Councillor, Beloit.

Fourth District.—Crawford, Grant, Iowa, Lafayette and Richland counties. Wilson Cunningham, Councillor, Platteville.

Fifth District.—Calumet, Fond du Lac, Manitowoc and Sheboygan counties. W. F. Zierath, Councillor, Sheboygan.

Sixth District.—Brown, Door, Kewaunee, Outagamie and Winnebago counties. H. W. Abraham, Councillor, Appleton.

Seventh District.—Buffalo, Jackson, Juneau, La Crosse, Monroe, Trempealeau and Vernon counties. Edward Evans, Councillor, La Crosse.

Eighth District.—Florence, Marinette, Oconto and Shawano counties. T. J. Redelings, Councillor, Marinette.

Ninth District.—Adams, Clark, Green, Lake, Lincoln, Marathon, Portage, Waupaca, Waushara and Wood counties. Jos. Smith, Councillor, Wausau.

Tenth District.—Barron, Burnett, Chippewa, Dunn, Eau Claire, Pepin, Pierce, Polk, Sawyer, St. Croix and Washburn counties. Rollo U. Cairns, Councillor, River Falls.

Eleventh District.—Ashland, Bayfield, Douglas, Forest, Iron, Langlade, Oneida, Price, Rusk, Taylor and Vilas counties. J. M. Dodd, Councillor, Ashland.

Twelfth District.—Milwaukee and Ozaukee counties. D. J. Hayes, Councillor, Milwaukee.

HONOR ROLL

Ashland County

ASHLAND—George W. Harrison; Carl O. Hertzman; Henry Arthur Sincock. BUTTERNUT—Albert August Axley.

Barron County

ALMENA—Edgar S. Christman. BARRON—Harry Marcus Coleman; Clark Crandall Post. PRAIRIE FARM—Hiram Allen Buell. RICE LAKE—Drexel Lowry Dawson; Edgar Jonas Knapp. TURTLE LAKE—William B. Cornwall.

Bayfield County

BAYFIELD—Franklin Marshall Hawley; Herman Gustave Mertens. WASHBURN—Parkes T. Trowbridge.

Brown County

DENMARK—Frank John Hager. GREEN BAY—Paul Mather Clifford; Robert Lewis Cowles; Donne Francis Gosin; Fabian Joseph Gosin; Herman Hendrickson; George F. King; Arthur James McCarey; John Edward McGinnis; Harry C. Mix; Walter E. Mueller; George Senn.

Buffalo County

GILMANTON—Arthur Dean Smith. MONDOVI—Milton Weston Hall; Earl L. Parmenter.

Burnett County

GRANTSBURG—Adolph Leonard Kyllo. SIREN—Lawrence H. Oliver. WEBSTER—George LeRoy Converse.

Calumet County

BRILLION—Keith Thomas Meyer. CHILTON—William Patrick Forkin; Donald George Hugo. FOREST JUNCTION—John Patrick Harkins. NEW HOLSTEIN—Alexander J. Berger.

Chippewa County

CHIPPEWA FALLS—Eugene P. Ellenson; Conrad William Wilkowske; George Mortimer Smith.

CORNELL—Henry Bush Beeson. HOLCOMBE—Royal Charles Rodecker. STANLEY—Hans C. Erickson.

Clark County

ABBOTSFORD—George Claude Devine. GREENWOOD—Frank Alfred Boeckmann; Frank Homer Kennedy. HUMBIRD—Samuel George Schwarz. OWEN—Sherman Merris Kyes.

Columbia County

PORTAGE—John E. Bentley; William Johnstone Thomson.

Crawford County

PRAIRIE DU CHIEN—Peter L. Scanlan.

Dane County

DEERFIELD—Merle H. Draper. MADISON—Smiley Blanton; Frank Favill Bowman; John Kendall Chorlog; James Philip Dean; Robert Drane; Carl A. S. Gunderson; Carl Samuel Harper; Herman Alfred Heise; William S. Middleton; Robert Clinton Montgomery; Norman Oscar Nelson; Ira Roscoe Sisk. MARSHALL—Clarke Bailey Devine. MENDOTA—William F. Lorenz. MIDDLETOWN—Martin Fred Du Frenne. STOUGHTON—Harry Anthony Keenan; Alfred Louis Olson. SUN PRAIRIE—William Ellsworth Allen; Howard Jerome Barry; Engelbert Theodore Krauss; John Edward Rueth.

Dodge County

BEAVER DAM—Leo Orrin Voorus; Enoch Palmer Webb. HORICON—Raymond Nicholas Nelson. LOMIRA—Leon Harry Flancher.

Door County

STURGEON BAY—Frederick Charles Huff.

Douglas County

SUPERIOR—Francis J. Broghammer; George Hall Conklin; William Edwin Ground; John Cornelius Kyllo; Walter Allan McEachern; Carl Jacob Rollefson; Charles B. Rydell; Richard Cecil Smith.

Dunn County

MENOMONIE—Anfin Egdall; Irving Van Vliet Grannis. RIDGELAND—Knute Albin Ruethin. WHEELER—Richard Albert Dreyer.

The fifth column shows 144,116 physicians in the United States. These figures are taken from the galley proofs of the new edition of the American Medical Directory, still in process of compilation, and do not include officers of the Medical Corps of the Army or Navy. It is estimated that the new directory will show a slight increase over the preceding one, or 145,000.

The population is based on the 1917 estimate made by the Bureau of the Census for use in connection with the Selective Service.

The tenth column gives 19,692 as the number of physicians who have been commissioned. As stated in the introductory, these figures do not include those who have been offered commissions but who have not yet accepted them, or whose acceptances have not been reported to this office. Neither, of course, does it include those whose applications are pending. We estimate the total of these two classes at about 2,000.

THE EFFECT OF PHOSPHORUS ON GROWING, NORMAL AND DISEASED BONES *

D. B. PHEMISTER, M.D.
CHICAGO

Since the experimental work of Wegner[1] in 1872, showing the effect of phosphorus on growing bones in animals, it has been used more or less extensively as a therapeutic agent in disorders of ossification. Almost no postmortem or other evidence, however, has been offered as to the exact changes which it brings about in the bones of man.

Wegner administered 1/400 grain of yellow phosphorus daily to young growing dogs, cats and chickens over considerable periods of time, and observed definite changes which in case of the long bones may be thus summarized: There was increased new bone formation in the diaphysis which was especially marked along the epiphyseal lines, leading to the formation of a dense layer in the ends of the shaft which varied in thickness with the length of the period of phosphorus administration. When the period was short, the zone of dense bone was narrow; but when prolonged, it was broad and in some instances included almost all of the trabeculated portion of the ends of the shaft. The cortex of the shaft was increased in thickness from both periosteal and endosteal new bone formation, but the change was not as striking as that in the end of the shaft except in the case of the chicken, in which the medullary cavity of the shaft was practically obliterated and the bones greatly increased in weight. Changes were also observed in the epiphyses. A dense narrow line of new bone formed about the periphery of each center of ossification. Adult bones were not affected by the administration of phosphorus. He found similar slight changes in a child with atrophic but otherwise normal bones which had received small doses of phosphorus during the two months previous to its death. The bones of three children dying of rickets which had been treated with phosphorus were studied and somewhat similar changes found in one of them. He was skeptical about the value of phosphorus in rickets which was regarded as a condition in which the power of depositing lime salts has been lost by the bony tissues. In this event the phosphorus would stimulate the still further formation of osteoid tissue, which would, however, remain unossified during the florid stage of the disease. Wegner also produced fractures and found that phosphorus stimulated the formation and ossification of callus, but he gives no instance of its use in delayed or nonunion in man.

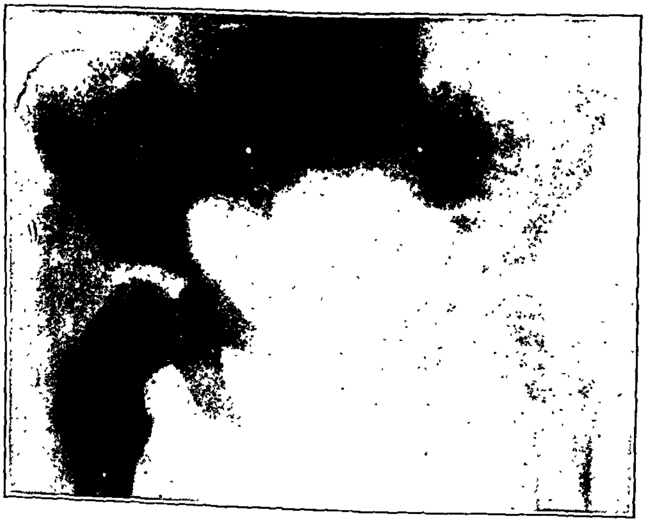

Fig. 1 (Case 1).—Perthes' disease of right hip before beginning administration of phosphorus.

Red phosphorus and phosphorus compounds, except large doses of calcium phosphate, produced no effects.

Kassowitz[2] repeated and confirmed Wegner's experiments and brought out the additional fact that from two to four times the dose of phosphorus that produces osteosclerosis leads to osteoporosis and the typical picture of experimental rickets. He used phosphorus extensively in rickets with good clinical results.

Kissel[3] experimented with phosphorus, and concluded that it produced no general changes in the bones; but he apparently used ten times the dose employed by Wegner, which explains the difference in results. Miwa and Stoeltzner[4] were also able to confirm the finding of Wegner in a few of their experiments, and Stoeltzner as a result of extensive clinical experience has been a firm advocate of phosphorus therapy in rickets.

Cod liver oil was used in the treatment of rickets before the introduction of phosphorus, and later the two substances were combined. Many regarded it largely as a convenient vehicle for the phosphorus and without any special therapeutic value. However, more recent studies in the calcium metabolism of healthy and rachitic children have tended to reverse this opinion.

Schabad,[5] in a series of articles, has maintained that phosphorus when administered alone in the usual therapeutic doses causes no increase in calcium accumulation in the body, and in some of the cases studied even accelerated its elimination. Cod liver oil alone causes a moderate increase, while cod liver oil and phosphorus cause a marked increase in the calcium accumulation. Lime salts, especially calcium lactate when given with cod liver oil and phosphorus, increase still further the calcium accumulation. Where the action is favorable there is not only an increased retention of the calcium intake, but a relative diminution in the calcium output both by the stools and by the urine. He concludes that the cod liver oil, not the phosphorus, is the primary active substance, and that the phosphorus acts secondarily by augmenting the accumulation that is started by the oil. Somewhat similar studies have been made by Schloss,[6] which tend to support these views.

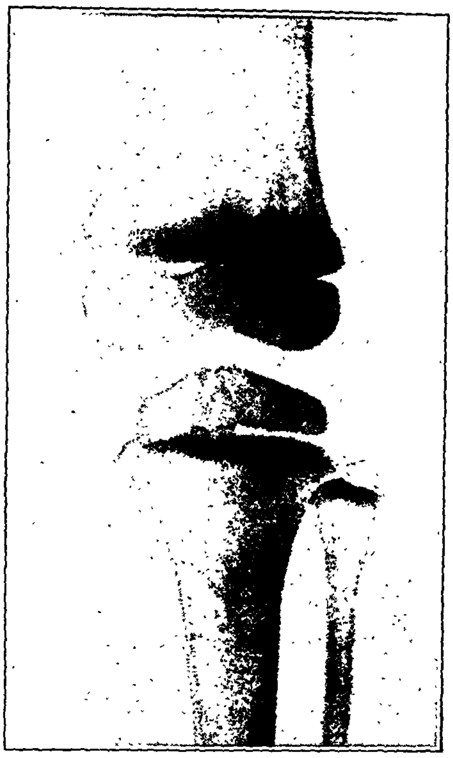

Fig. 2

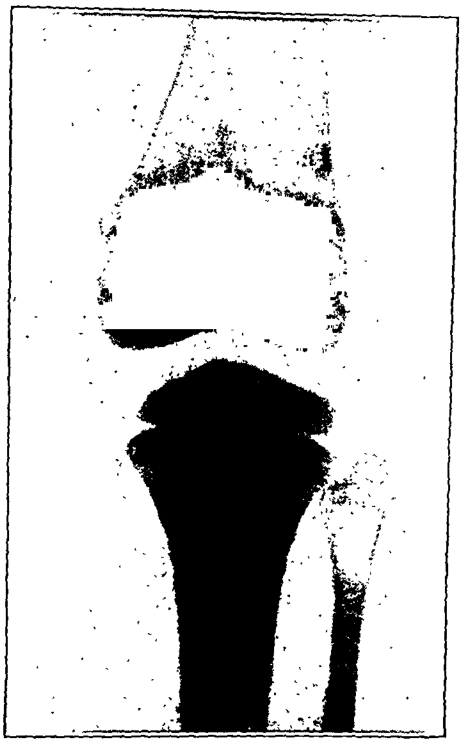

Fig. 3

Fig. 2 (Case 1).—Right knee eight months after beginning treatment with phosphorus. Note heavy, broad shadow in the end of the shaft of each bone.

Fig. 3 (Case 1).—Four months after discontinuing phosphorus. Growth has continued; an unexpected finding is that a second line has formed in the immediate zone of growth along the epiphyseal cartilage which is of about the same density and thickness as the first.

As 98 per cent. of the calcium of the body is stored up in the bones, they should show a variation in calcium content in case of an increase or decrease in the amount retained in the body. This can be determined either by studies at necropsy or by roentgen studies of the bones in the living. No evidence of either kind is offered by Schabad or Schloss in support of their claims. Consequently the roentgenographic studies of the following cases in which phosphorus alone was administered are of interest.

Case 1.—A. P., aged 4, was first seen in November, 1915, with the typical picture of Perthes' disease of the right hip of six months' standing (Fig. 1). The joint was immobilized for three months by a plaster-of-Paris cast, and phosphorus, 1/200 grain, was given three times a day, in order to determine its effect on the diseased epiphysis of the head of the femur. Roentgen-ray studies were also made of other regions in order to study the effects on the normal bones. The phosphorus was continued for eight months, at which time Figure 2 was taken of the right knee. It shows a heavy, broad shadow in the end of the shaft of each bone, being broadest in the femur where the longitudinal growth is greatest. The cortices of the shafts do not appear to be thickened. The epiphyses of all three bones show a fairly dense narrow shadow about the periphery of the centers of ossification. The drug was then stopped, and Figure 3 shows the condition four months later. Growth has continued, and the epiphyses have thereby been carried beyond the lines in the ends of the shafts, which lines are also narrower and less dense than in Figure 2. An unlooked for finding is that a second line has formed in the immediate zone of growth along the epiphyseal cartilage which is of about the same density and thickness as the first. The epiphyses show a second shadow of a layer of new bone outside of the dense layer formed during the period of phosphorus administration. This is best seen on the epiphysis of the fibula, and the sides of the epiphysis of the femur.

Roentgenograms at the end of another four months (Fig. 4) show the same two sets of lines in the ends of the shafts and epiphysis; but they are much fainter, narrower and more widely separated than at the previous examination. The phosphorus was then administered for five weeks, and seven and one-half months later roentgenograms were again taken (Fig. 5). Three faint lines are now visible in the *ends* of the shafts about the knee; one deep in the shaft from the

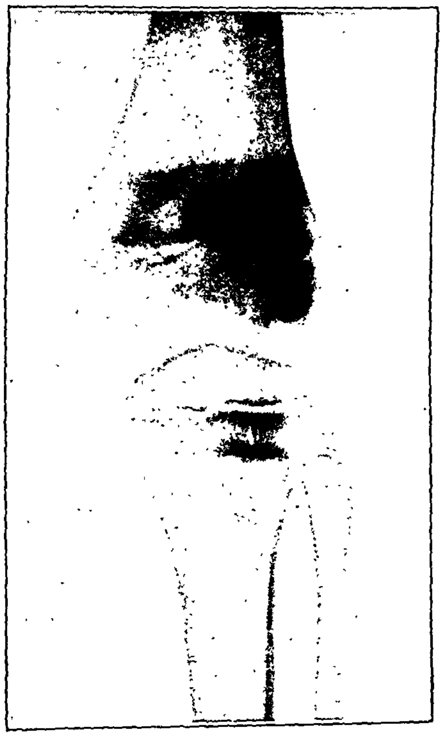

Fig. 4

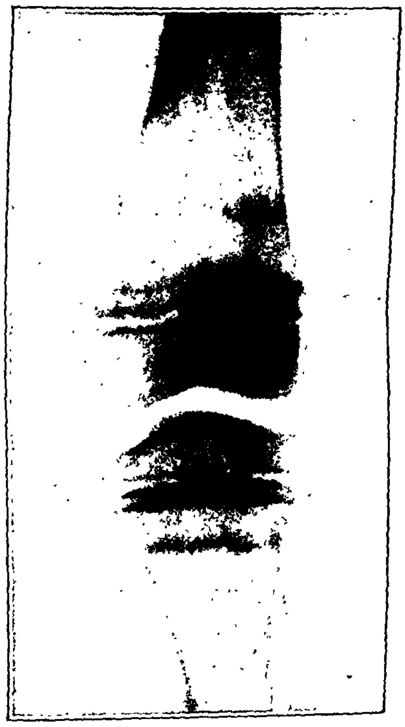

Fig. 5

Fig. 4 (Case 1).—Four months after Figure 3 was taken. Of special interest in Figures 4 *and* 5 *is* the evidence of continued bone formation in the end of the shaft over a prolonged period after the phosphorus had been stopped.

Fig. 5 (Case 1).—Seven and one-half months after Figure 3 was taken.

---

5. Schabad: Ztschr. f. klin. Med., 1909, **57**, 454; *1909*, **58**, *94*; 1910, **59**, 435; Jahrb. f. Kinderh., *1910*, **72**, 1.

6. Schloss: Jahrb. f. Kinderh., 1915, **82**, 435; 1916, **83**, 46; Monatschr. f. Kinderh., 1914, **13**, 291.

first administration, a second near the epiphysis from the second administration, and a third in the recent zone of growth along the epiphyseal cartilage. The inner line formed in the epiphyses from the first administration is still faintly visible, but no middle or outer dense lines are seen. The same changes were found on roentgen examination of the ends of other long bones.

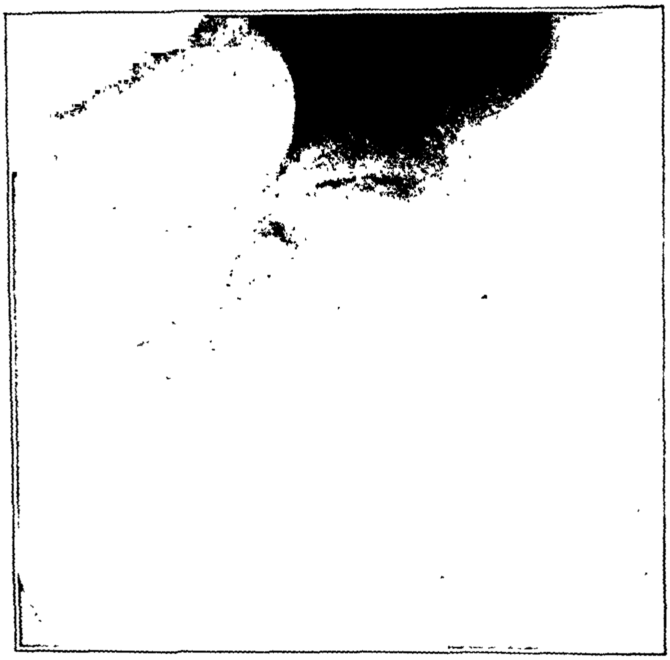

Fig. 6 (Case 1).—Affected hip two and one-half years after onset of disease. Phosphorus appears to have had little influence on the course of the disease.

The cause of the continued, although less marked dense bone formation in the end of the shaft along the epiphyseal line, over a prolonged period of time after the phosphorus had been stopped is problematical, but the following two factors are to be considered: First, that phosphorus may be retained in the body and exerts a cumulative action, and second, that the excessive calcium salts stored up in the form of bone in the immediate vicinity may act as a stimulus and cause the dense bone formation. In favor of the former is the observation of Schabad's that wherever there was calcium accumulation there was also an increase in phosphorus retention. Such accumulation is, however, in the form of phosphates, and there is no evidence of the storing up of the element phosphorus as such in the body. In favor of the latter there are no anatomic or roentgen-ray observations; but the metabolic studies of Stoeltzner and Etienne show that moderate doses of calcium salts cause both a relative and an absolute increase in the amount of calcium retained. It is possible that the excessive lime salts stored up in the form of bone, which are constantly being liberated, act as a stimulus and lead to the dense new bone formation in the zones of growth. This may explain the manner of action of calcium phosphate as observed by Wegner.

It is of interest to note that the phosphorus apparently had no influence on the course of the disease for which it was given. The epiphysis gradually broke down until it was eventually almost completely destroyed and the neck was greatly deformed. Active symptoms subsided after about twelve months, leaving the hip joint markedly stiffened, and Figure 6 shows the condition two and one-half years after the onset. Meager results were to be expected, as Perthes' disease is in all probability an epiphysitis of bacterial origin, and as the phosphorus has little influence on the slowly ossifying normal epiphysis.

A second case shows the influence of phosphorus on a marked disturbance of the longitudinal growth of the shafts of the bones of one limb, and on the normal bones of the other limbs:

Case 2.—G. C., boy, aged 7½ years, entered the Presbyterian Hospital, July 18, 1915, with dyschondroplasia (Ollier) of the left lower limb. He had limped since the second year, and the left limb, which was otherwise strong and free from symptoms, had gradually grown much shorter than the right. An operation involving bone transplantation for supposed bone cyst had been performed on the upper end of the femur one year before, with infection, and a resulting fistula that had not healed. The patient was a well developed, healthy boy except for the left lower extremity, which was 3½ inches shorter than the right. Both thigh and leg were involved in the shortness, but the foot was almost free, as it was only slightly smaller than the right. The musculature of the limb was well developed, and all the movements were normal. There was a discharging fistula 3 inches beneath the greater trochanter. The ends of the shortened shafts of the femur, tibia and fibula were slightly enlarged and uneven. Roentgen examination of the ends of the bones revealed the epiphyses approximately normal, but the ends of the shafts for a distance of 2 to 3 inches beyond the epiphyseal lines were expanded and cast very faint shadows, which were streaked by irregular longitudinal lines and dotted irregularly by uneven shadows. This change was most marked in the lower ends of the femur (Fig. 7) and tibia. The upper end of the femur showed a coxa vara with a broadened neck casting a faint shadow and the outline of the necrotic transplant below in the irregular but dense shaft which had been formed about it.

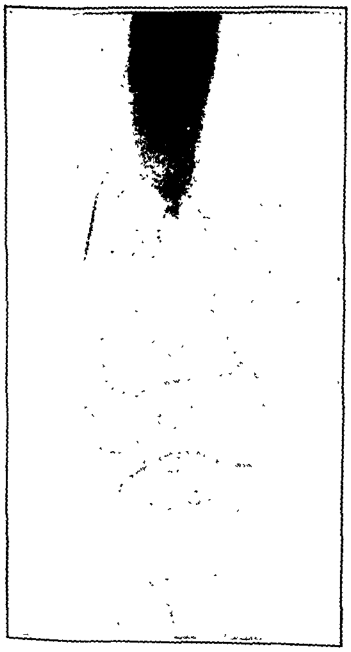

Fig. 7

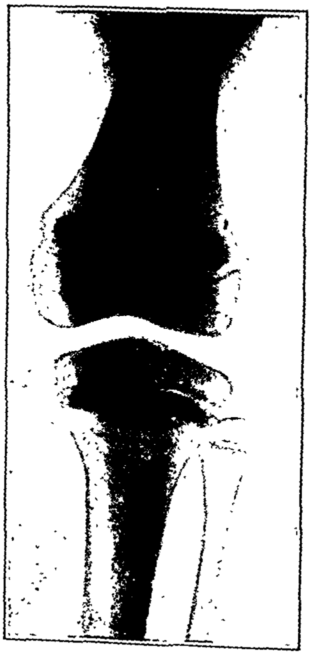

Fig. 8

Fig. 7 (Case 2).—Dyschondroplasia (Ollier). Note the irregular longitudinal lines and the irregular uneven shadows in the lower end of the femur and tibia particularly.

Fig. 8 (Case 2).—Effect of prolonged administration of phosphorus on dyschondroplasic bone.

The infected transplant was removed, and at the same time for diagnostic purposes a strip was excised the entire length of the diseased area of the lower end of the shaft of the tibia. It showed that the end of the shaft was filled with a mass of hyaline cartilage with only a thin streaked bony cortex about the periphery, and islands of calcification with beginning ossification were scattered irregularly throughout, making the dotted shadows in the roentgenograms. The condition arises from a dysplasia of the epiphyseal cartilage leading to a piling up of cartilage or an enchondromatous condition in the ends of the shafts and usually affects the bones of one or two extremities. It was decided to try the effects of phosphorus on the diseased condition; so after the hip wound had healed, the patient was given $\frac{1}{200}$ grain in pill form twice daily for three months. Roentgenoscopy revealed moderate changes similar to those in Figure 2 of the preceding case and also including the ends of the affected bones of the left limb. The phosphorus was discontinued for twenty-six months, at which time the only remaining effects of its administration, as shown by the roentgen ray, were the narrow, feeble, transverse shadows in the ends of the shafts at considerable distances from the epiphyseal lines. One hundredth grain pills were then given twice daily and continued fairly regularly for eight months, at which time roentgenograms were again taken.

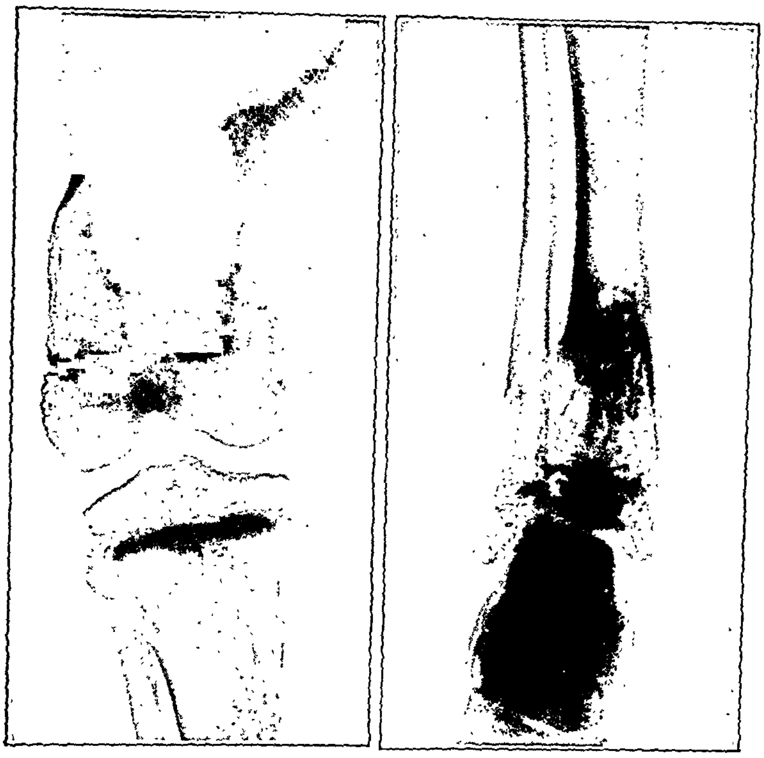

Fig. 9 Fig. 10

Figs. 9 and 10 (Case 2).—Effect of prolonged administration of phosphorus on dyschondroplasic bone.

Figure 8 shows the effect in the normal right limb, where the broad, heavy shadows of the shaft ends represent the bone formation from the recent administration. The narrow line some distance away in the end of the tibia is from the previous administration; but no traces of it are to be seen in the end of the femur or in the epiphyses. In the left limb (Fig. 9) there are no traces left of the first administration except a very faint line seen in the upper end of the tibial shaft.

From the second administration there are zones along the epiphyseal lines and marked enlargement of the irregular spots in the diseased ends of the shafts. The upper end of the tibia where the disease is not marked shows an even broad line, but the lower end of the femur, where the changes are extensive, casts a very irregular juxta-epiphyseal shadow. In its mesial portion there has been little growth along the epiphyseal line, which has produced some bowing of the leg; but the shadows representing numerous islands of the zone of calcification carried upward in the cartilaginous mass have markedly enlarged. This is due no doubt to ossification in and about them and not to a growth of the islands of calcification. The changes are especially well shown in the lower ends of the tibia and fibula, where shadows are seen in the epiphyses from growth about included islands of calcified cartilage (Fig. 10). The transverse growth of the shafts, including the diseased regions, has continued, as seen by comparing Figure 7 with Figure 9, which was made two and one-half years later; but there is little evidence of the influence of the phosphorus on it.

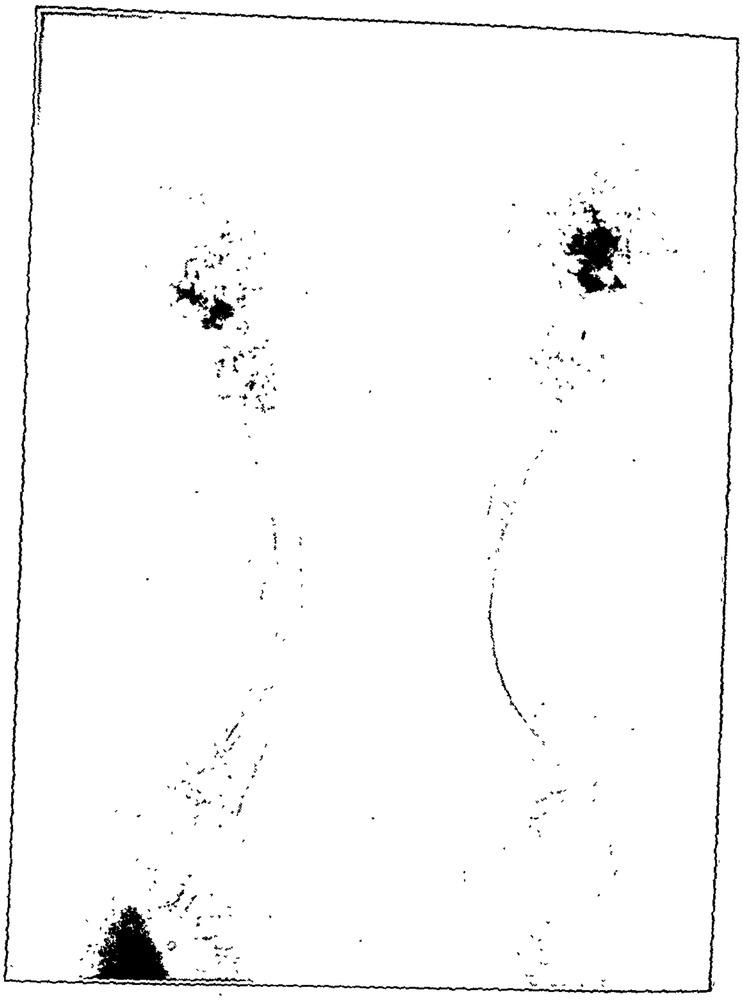

Fig. 11 (Case 3).—Limb bones in osteogenesis imperfecta. The shafts are relatively narrow, and the cortices are very thin.

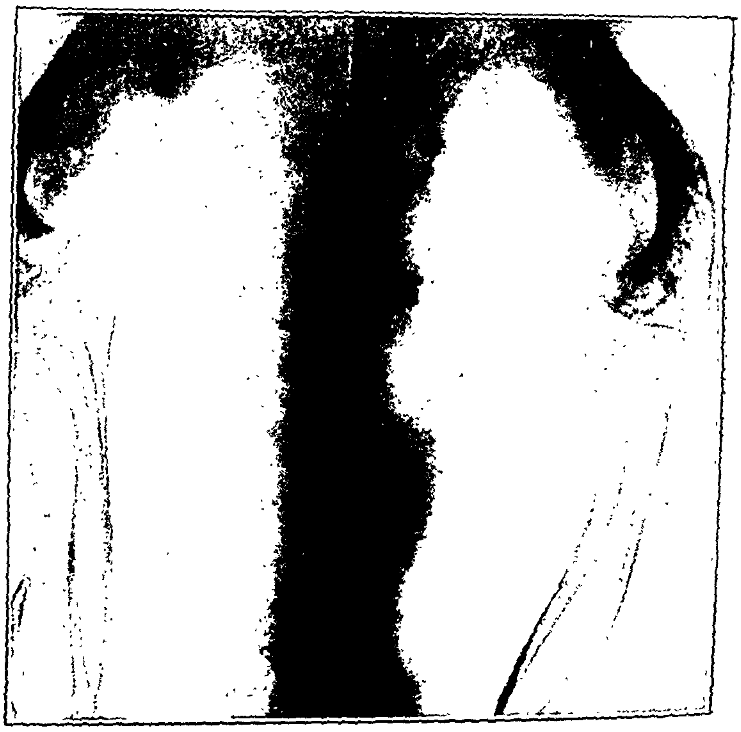

Fig. 12 (Case 3).—Limb bones in osteogenesis imperfecta. The shafts are relatively narrow, and the cortices are very thin.

It is doubtful if the effect of the phosphorus has been of any value to the patient, as there has been no relative increase in the length of the affected limb. It is conceivable, however, that the prolonged use of phosphorus in enchondromas showing areas of calcified cartilage might eventually lead to their complete ossification.

The following case shows the marked effect of phosphorus on both the longitudinal and transverse growth, where a congenital disturbance of bone growth was present:

Case 3.—W. N., boy, aged 8, was first seen in May, 1913, presenting the usual picture of osteogenesis imperfecta. He weighed only 25 pounds and had suffered numerous fractures of the bones of the frail extremities since birth which, coupled with a hyposcoliosis, had resulted in marked deformity. He was unable to stand and showed about the mental development of a 4 year old child. Roentgenograms of the limb bones (Figs. 11 and 12)) revealed fairly long but very narrow shafts, the cortices of which were very thin. As a result of the fractures there were marked curvatures and remnants of several old calluses. The epiphyses were relatively large, and their centers of ossification had appeared normally. Epiphyseal lines were distinct except in the lower ends of the femora, where, as a result of injury, they had become obliterated, resulting in marked shortening of the shafts, especially the right one (Fig. 19).

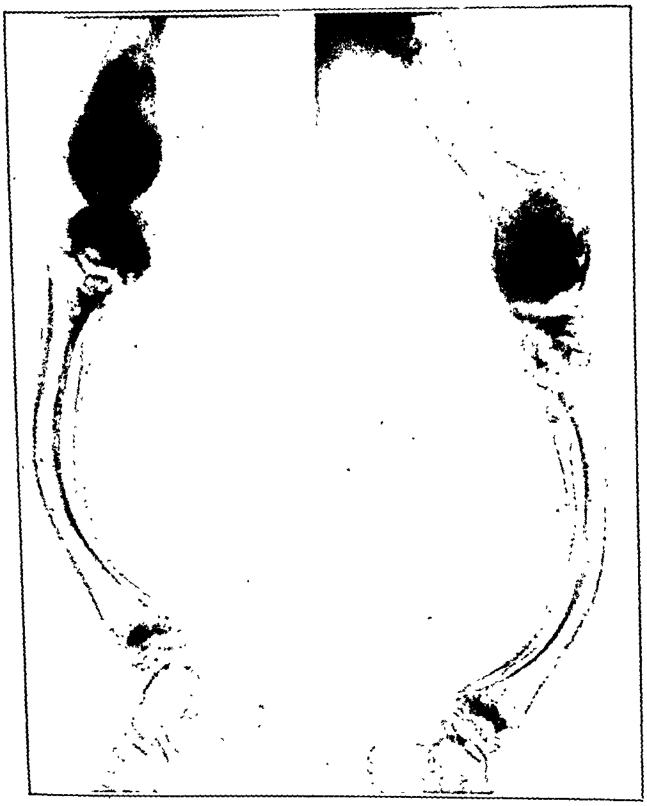

Fig. 13 (Case 3).—This and the following illustrations show the bone changes following prolonged administration of phosphorus in a case of osteogenesis imperfecta. There has been marked stimulation of osteogenesis which has led to transverse growth of the shafts—the process chiefly affected in the disorder—as well as to longitudinal growth and growth of the epiphyses. In this illustration, marked transverse growth of the tibiae and fibulae is shown, with no signs of recent fractures.

The patient was put on phosphorus pills, 1/200 grain, three times a day, which were continued quite regularly for twenty-six months, when he was again seen. There had been considerable general improvement and a gain in weight of 5 pounds. He was now able to sit, and used the arms more freely, which had resulted in a number of bone injuries during the periods. Roentgenoscopy revealed marked phosphorus changes. There were shadows at the ends of the shafts varying in density and breadth according to the normal rate of longitudinal growth for the region, marked increase in the transverse diameters of the shafts and denser shadows about the cortex of the centers of ossification in the epiphyses and in the short bones of the hands and feet and of the patellae. The tibiae and the fibulae (Fig. 13) showed marked transverse growth with no signs of recent fractures. The broad dense shadows at the lower ends of the shafts showed the preponderance of growth in this region. There were no shadows in the lower metaphyses of the femora, owing to the absence of longitudinal growth from obliteration of their epiphyseal lines. There were marked changes in the upper extremities (Fig. 14), where shadows from the longitudinal

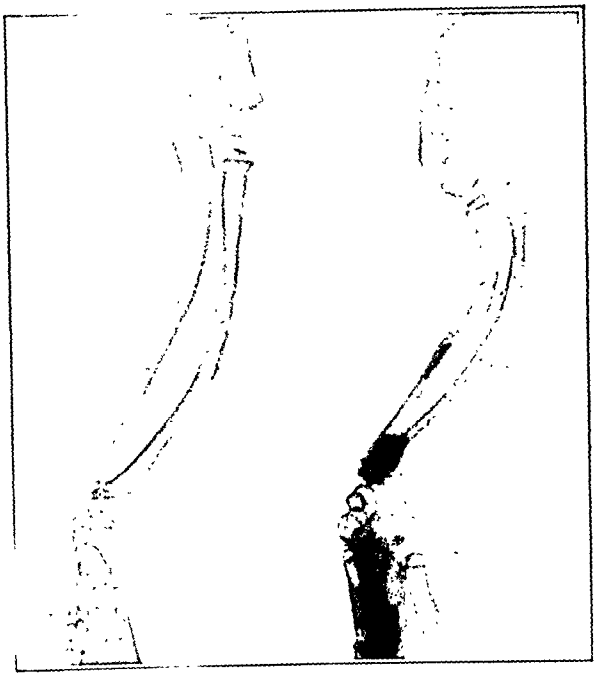

Fig. 14 (Case 3).—Marked changes in the upper extremities.

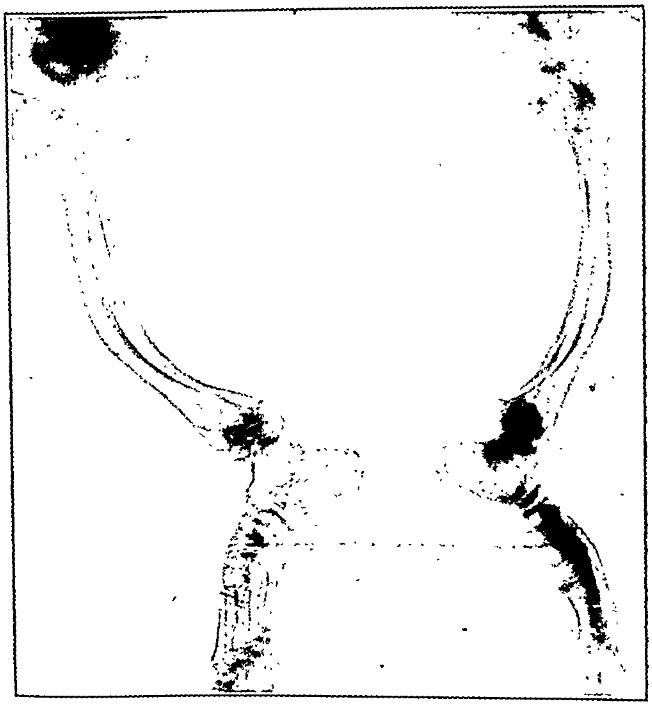

Fig. 15 (Case 3).—Fading of the shadows in the ends of the shafts, and absence of dense shadows in the zones of continued growth.

growth were broadest in the lower metaphyses of the radius and ulna. The transverse diameters were greater in the bones of the right arm. This was no doubt due to disuse of the left arm, resulting from fractures, two of which had occurred in the humerus and one in the radius and ulna, those of the humerus being not yet fully united.

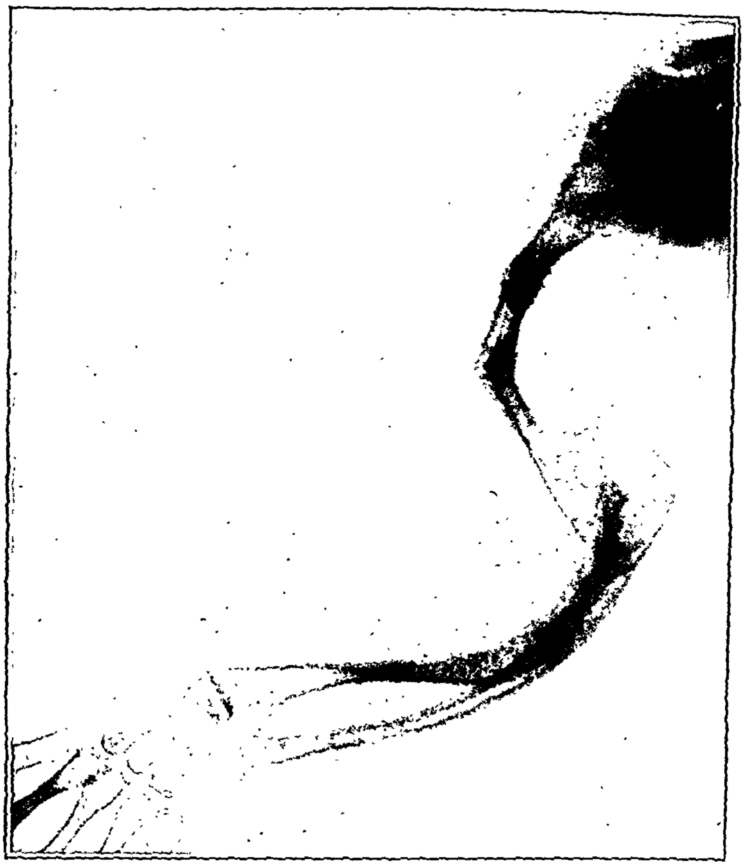

Fig. 16 (Case 3).—Left humerus, showing the two fractures with greater angulation and broader unossified intermediary calluses.

The dose of the drug was then changed to 1/150 grain twice daily, but the mother stopped giving it after about three months. The child was next seen one year later. Roentgenoscopy revealed marked fading of the shadows in the ends of the shafts (Figs. 15 and 16) as shown in previous plates, and no dense shadows formed in the zones of continued growth. The diameter of the shafts and thickness of the cortices had remained about the same. Inner markings from the previous administration were seen in some of the epiphyses and short bones of the hands and feet. The left humerus (Fig. 16) showed the two fractures with greater angulation and broader unossified intermediary calluses than in the previous plate. During the nine months that the phosphorus was discontinued there was more rapid absorption of the previously deposited bone than occurred during like intervals from healthy bones of the first two cases reported.

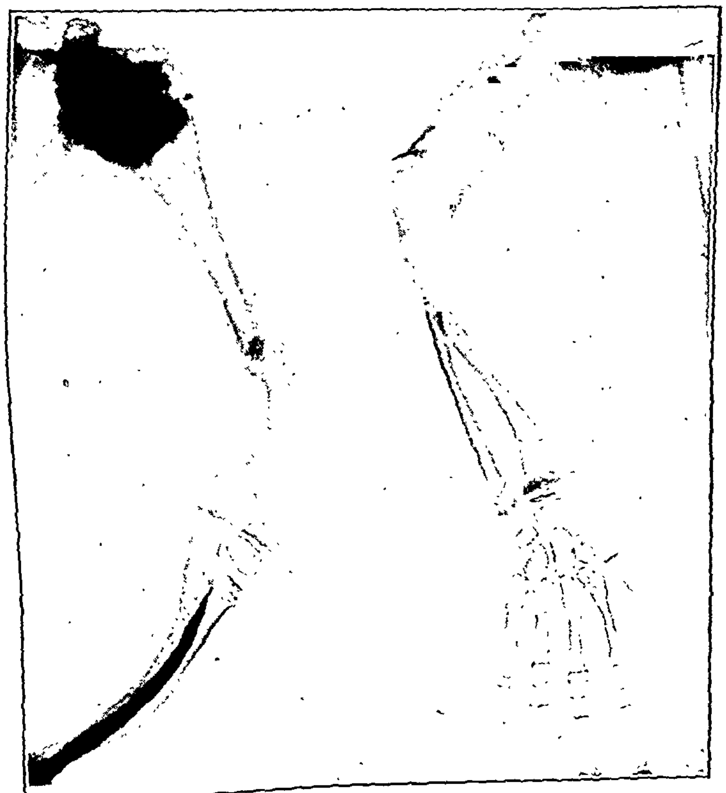

Fig. 17 (Case 3).—Phosphorus changes less extensive than in the first period.

The patient was again put on 1/150 grain of phosphorus twice daily, which was continued for eighteen months, when he was again examined. He was much more active both physically and mentally and could creep about, but was still unable to walk. He weighed 35 pounds, which was a gain of 10 pounds during the four and one-half years that he had been under observation. His mental development had been rapid, and he was doing third grade work in school. The deformity of the left arm had increased, and it was much less serviceable than the right. Six months before he had fractured the right arm, which was treated by a splint with healing. Roentgenograms were again taken, which showed phosphorus changes in the previously mentioned locations; but they were relatively less extensive than for the first period (Figs. 17 and 18). This was doubtless due to the smallness of the dose for his weight and age. The right humerus was relatively large and showed a bony callus at the seat of the fracture. The shaft of the left humerus was small, and the lower fracture shown in the previous plate was still ununited. The upper one had united, and its callus had almost entirely disappeared. In the picture of the pelvis and thighs (Fig. 19), the effects of the different administrations are especially well shown by the lamellae on the crests of the ilia. The dose of phosphorus was increased to 1/100 grain twice daily. Care must be exercised when it is used over such long periods of time in order to avoid the development of chronic phosphorus poisoning, in which, according to Wegner, there is necrosis of the parenchyma and subsequent fibrosis with contraction of the liver and kidneys, and to a less extent of other organs.

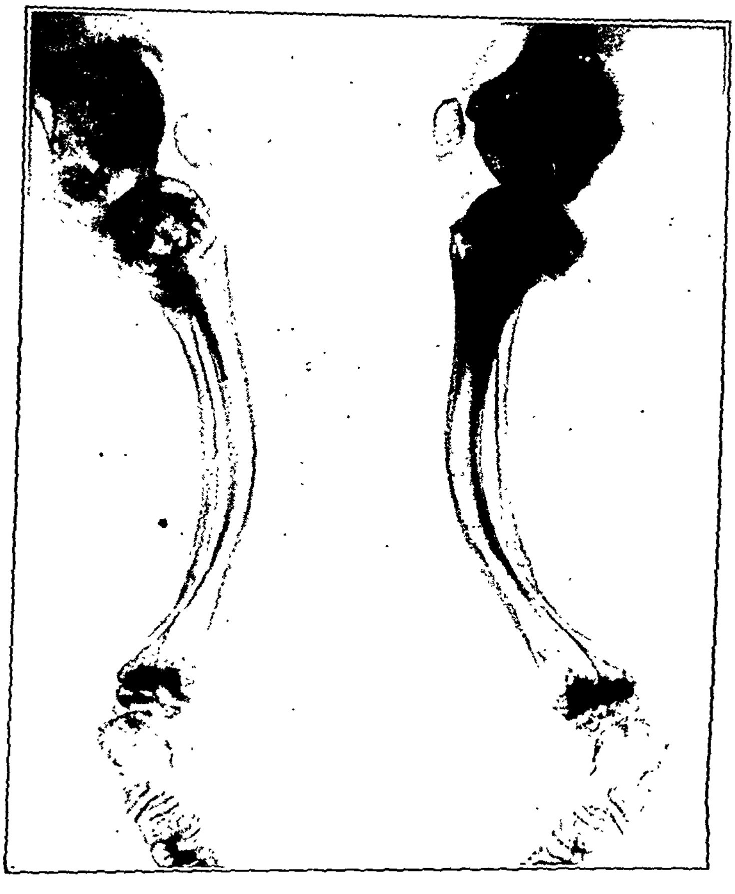

Fig. 18 (Case 3).—Phosphorus changes less extensive than in the first period.

The therapeutic value of phosphorus in this case is unquestioned. While it has not removed the underlying cause, osteogenesis has been markedly stimulated, both in the fibrous and enchondral processes of bone formation. This has led to transverse growth of the shafts, which process is chiefly affected in the disorder, as well as to longitudinal growth and growth of the epiphyses.

These findings show that phosphorus affects the normal bones of children in much the same way as described by Wegner for experimental animals. The effects on enchondral bone growth is especially well marked. No definite increased transverse growth could be made out, but if slight it would easily escape detection by means of the roentgen ray, especially as the technic varied with each set of plates. Also for some time after the phosphorus is stopped there is a continued but less marked overproduction of bone in the juxta-epiphyseal region of the shaft which is probably due either to the cumulative effect of phosphorus or to the stimulating influence of the excessive stores of calcium salts in the neighboring bone.

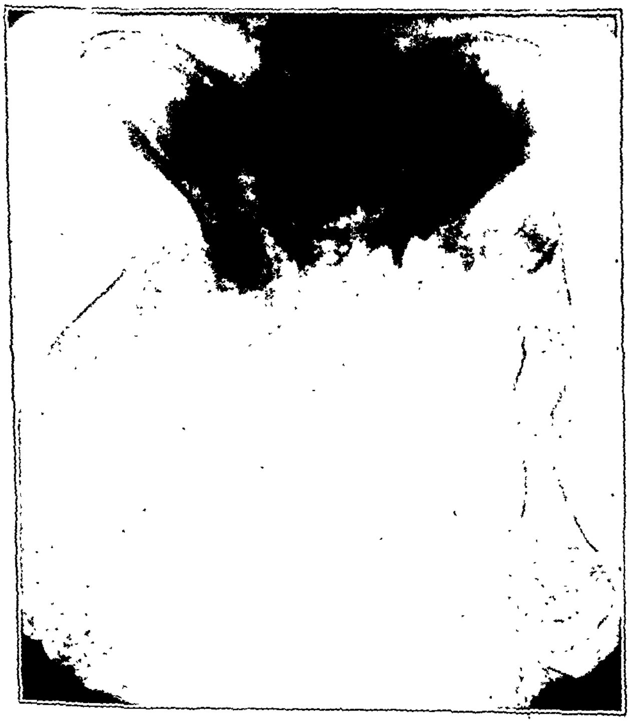

Fig. 19 (Case 3).—Effects in the pelvis and thighs.

COMMENT

The diseased bones showed certain variations. In osteogenesis imperfecta, the transverse growth was as strikingly affected as the *longitudinal*. All fractures occurring during the period of observation healed except one at the middle of the left humerus, which occurred during the period of interruption of the phosphorus, an inactive stage of nonunion being established before renewal of the drug. Judging from the general effect it produces, phosphorus if given early in fractures during the active period of repair should stimulate callus formation and ossification. In nonunion, however, when the natural reparative impulses have been exhausted, little should be expected from its use.

Roentgen-ray studies of the bones during the administration of phosphorus alone and with other substances in rickets should be of interest. These observations show clearly that phosphorus when given alone has a marked stimulating effect on bone production and consequently of calcium accumulation in the normal zones of growth, and speak against the assertions of Schabad relative to calcium metabolism in healthy children.

During the florid stage of rickets, the bony tissues have lost the power of depositing lime salts; and as phosphorus is presumably unable to restore this power, no appreciable effect from its administration would be detectable by means of the roentgen ray, although it may increase the amount of osteoid tissue formed. During the healing stage, when the power of laying down lime salts begins to return, the phosphorus would stimulate the formation of osteoid tissue and consequently increase the amount of bony tissue formed. It must be remembered that during the healing stage of rickets, from the rapid ossification of osteoid tissue piled up in the metaphysis during the florid stage, a condition forms which roentgenologically resembles very much the phosphorus changes in normal bones.[7] Phosphorus administration would intensify this condition.

A CONSIDERATION OF SOME DRIED VEGETABLES

WITH SPECIAL REFERENCE TO THEIR NITROGEN AND CALCIUM CONTENT *

MAURICE H. GIVENS, Ph.D.
Seessel Research Fellow in Physiological Chemistry, Yale University
NEW HAVEN, CONN.

From an economic standpoint it is highly desirable, particularly at this time when the transportation of foods occasions unusual difficulties, to eliminate as much water as possible from them and thus reduce their weight and bulk. This furnishes the justification for the attempt to use desiccated foods. Any propaganda for the widespread use of foods prepared in novel ways ought to be supported by scientific evidence of its importance from a physiologic standpoint.

For arctic explorations a supply of vegetables is considered desirable. In some expeditions this has been obtained by the use of desiccated green foods. During the Civil War such dried vegetables as were available were used. At present the various governments are using desiccated foods. The United States Food Administration has directed much effort during the past year in impressing on the minds of the people the value of drying foods. Farmers in this country years ago started drying such products as string beans. A successful community drying plant is no longer an experiment but an institution.[1] The drying of fruit likewise received attention from the Department of Agriculture years ago.[2] The possibilities of conservation by desiccation are obvious.

In considering the value of a food today, its inorganic constituents should receive attention as well as its protein, fat, carbohydrate and vitamin content. Years ago, Bunge[3] and other physiologists emphasized especially the physiologic importance of the mineral content of foods. The significant rôle which the inorganic constituents of foods may play has of late been demonstrated experimentally in more than one way, notably through the study of synthetic dietaries in which one or more inorganic elements were lacking or present in unsuitable proportions.[4]

[3] Bunge, G.: Lehrbuch der physiologischen Chemie, Leipzig, 1897.

Sherman's[5] determinations of the inorganic constituents of a great many foods and also his compilations of recorded analyses are of unusual value to all students of nutrition. He in particular and later Blatherwick[6] have called attention to the significance of the acid and base forming constituents of foods. Forbes[7] has analyzed the ash of a great many foods, but most of his data relate to animal feeds.

Recently Courtney, Fales and Bartlett[8] reported statistics of the inorganic constituents of a number of vegetables subjected to definite conditions of cooking. These authors were particularly interested in determining to what extent cooking by different methods removed the available inorganic components of the foods, bearing in mind the use of green vegetables for their iron and calcium content in infant nutrition.

The student of dietetics recognizes that were it not for the use of milk, eggs and a few green vegetables, our food intake would ordinarily be very deficient in available lime. The present study was planned to supplement our somewhat meager knowledge regarding the composition of desiccated vegetables.

METHODS OF DRYING

Carrots and potatoes were peeled, care being taken not to contaminate the freshly cut surfaces with dirt; they were then weighed, sliced thin, and dried. All other vegetables were handled in an edible form; that is, inedible portions were removed, and the remainder washed thoroughly in cold running water to remove all traces of adherent soil. All vegetables were either dried on a piece of cheesecloth or in a small sieve on an ordinary steam-heated radiator at from 65 to 70 C. (149 to 158 F.).

At the temperature here used in drying, it is wise not to keep those vegetables containing much starch and sugar on the radiators longer than from two to three days, because they then begin to darken. The loss of water in producing these air-dried products was estimated as given in the table.

ANALYTIC PROCEDURES

The moisture still remaining in the air-dried products was determined by drying for from four to five hours in an oven at from 96 to 97 C. (204.8 to 206.6 F.). This temperature in some instances caused a slight darkening; but after many trials at different temperatures, it seemed the best to adopt as a working basis for this analytic procedure.

Ash was determined in the ordinary way on the air-dried material; nitrogen by Kjeldahl's method likewise, and calcium by McCrudden's[9] method. Before the calcium was determined, the ash was always taken down to dryness on the water bath from three to five times with hydrochloric acid to cause the traces of silica to flock out for removal.

THE LOSS OF WATER IN DRYING

The water content of vegetables is so variable that we only report figures on the basis of the solids found after drying as described. Values for raw edible portions mean nothing when the possibilities for a plant to lose water are so many. For example, variations in water content of a green vegetable may be due to the soil, weather at the time of harvesting, manner of shipment, manner of "handling" by the various dealers, period of time from harvest to consumption, and many other conditions.

NITROGEN

The nitrogen content of the dried vegetables is at best only a rough index of their content of protein. The increase in the concentration of protein as the result of drying is most striking; for example, the nitrogen content estimated on the basis of raw sweet potato is 0.3 per cent.; on the dried product it is 1.06 per cent.; in raw spinach it is 0.45 per cent.; in the dried, 4.58 per cent.

PERCENTAGE COMPOSITION OF VEGETABLES, ARRANGED ACCORDING TO DECREASING NITROGEN CONTENT

* *Product of the Mrs. O. H. Harriman Laboratory, New York.*

** *Prepared by Dr. H. C. Gore, Bureau of Chemistry, U. S. Department of Agriculture.*

The variation in nitrogen according to the plant or parts of the plant is striking. The starch plants, as potatoes and carrots, notwithstanding a high solid content on drying, have a low protein content. Spinach, Swiss chard, lettuce, celery and cabbage serving as vehicles of roughage and flavor, with a high water content, contain a relatively high percentage of nitrogen in the dried material. Intermediate between these two groups stands the string bean, in which the protein is concentrated ten times or more by drying.

In addition to the variation in nitrogen content according to the plant, there is a noticeable difference in the amount of nitrogen in the different parts of the same plant. Dried Carrots I had a nitrogen content of 1.19 per cent., while the tops from these carrots contained 1.95 per cent. According to a calculation from the tables of Atwater and Bryant,[10] the solids of beets contain 2.04 per cent. of nitrogen, whereas the sample of dried beet tops here analyzed contained 4.35 per cent. In the case of String Beans III, the nitrogen value of the beans was 4.98 per cent., while of the pods it was 3.09 per cent. In other words, the dietetically unimportant or waste parts of some vegetables contain almost as much nitrogen as, and in some cases more than, the important part of the vegetable, that is, for human consumption.

Notwithstanding these apparently high nitrogen values of some dried foods, it is doubtful whether they are significant from the standpoint of protein intake. Unless we alter our mode of cooking or resort to the use of dried material, it is hardly probable that an individual on his ordinary mixed diet would consume at one meal, in addition to other food, more than from 100 to 200 gm. of the cooked edible portion of any of the vegetables. However, it is not beyond the realm of possibility to dry and comminute the vegetable so finely that one could easily cook the dried material in half of its original water content. In fact, we have cooked our dried carrots in an amount of water equivalent to that driven off from them during the drying process, and have subsequently concentrated the mixture to a palatable consistency. This would have been impossible if the same vegetables had been cooked in their original form.

INORGANIC CONSTITUENTS

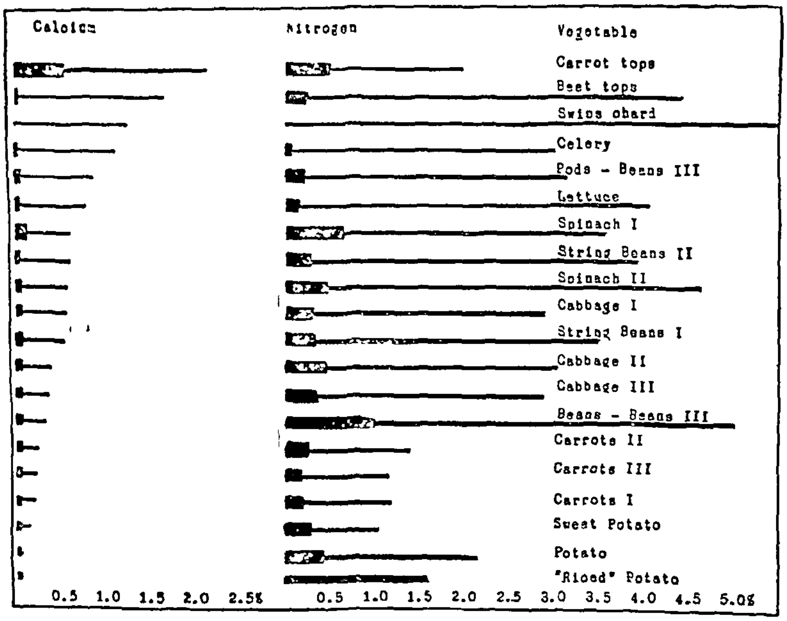
A glance at the table shows that a high percentage of inorganic constituents is characteristic of the green vegetables. This statement applies likewise to the calcium content. This alone, if there were no other reasons, would warrant a consideration of these materials as adjuvants to the dietary of the growing individual. We noted by comparative qualitative tests that the green foods had a preponderance of iron over the other vegetables. Their value as a source of iron cannot be overlooked when it is remembered that a quart of milk, one of the most valuable foods, contains only 1 or 2 mg. of this element. The last column of the table shows the calcium in percentage of the total inorganic content of the vegetables.

LOSSES BY COOKING AND DRYING

Attention is called to the possible loss of inorganic elements in the method of cooking vegetables. Snyder[11] studied the loss in cooking potatoes, carrots and cabbage under various conditions. Using ordinary methods of cooking, he showed that there was a decided loss in the inorganic constituents, as well as other components, in some instances as much as 50 per cent. Wardall[12] has estimated the loss in carbohydrates in preparing "thrice washed" vegetables for diabetics. Most recently Courtney, Fales and Bartlett called attention to the loss in minerals, by boiling, in preparing vegetables for children. They recommend the steaming of foods.

As is shown in the table, the "riced" potato contained a smaller amount of inorganic components, particularly calcium, than the other potato. This may be due either to the soil in which they were grown or to the method of preparation for drying. These "riced" tubers were steamed before drying to destroy the enzymes which cause the raw potato to darken when exposed to the air. The calcium content of the potato is very low, and to remove any of it in the preparation for drying is a serious objection. This fact must be borne in mind if potatoes are to be dried extensively in this country. With our material there was only a slight darkening when the time between slicing and exposure to radiator heat was reduced to a minimum. In fact, the darkening was so slight that it could not be detected after the dried product was ground.

The physiologic importance of calcium in the feeding of growing organisms is now universally recognized. No other food supplies as much lime as milk. Some of the vegetables here analyzed, if fed in conjunction with milk or other foods, as the cereals, which are decidedly lacking in lime, will increase the available lime in the diet. There is a paucity of studies on the physiologic value of calcium in vegetables. From investigations conducted in this laboratory during the past year, the indications are that for at least two vegetables, spinach and carrots, the available lime is not as well utilized as that from milk or lime salts. Courtney, Fales and Bartlett indicate that in their experience one child, somewhat rachitic, showed an improved mineral balance on the addition of spinach to its dietary. The analyses here reported indicate the amount of lime present in some vegetables, which might become desirable as supplementary sources of calcium.



Calcium and nitrogen content of fresh and of dried vegetables: heavy lines, percentage content of calcium or nitrogen in the fresh vegetable; light lines, concentration of these elements in the same products dried.

SUMMARY

The quantity of water lost by the foods dried in this series is in accord with the values reported in Atwater and Bryant's analyses. The vegetables here studied contained from 71 to 97 per cent. of water.

In the case of some of the vegetables, the nitrogen content in terms of the dried product is in striking contrast with that of the original material, owing to the large losses of water.

Some of the materials are possible, valuable and hitherto unappreciated sources of lime. The calcium

mice of from 15 to 20 gm. weight against 0.1 c.c. of an 18 to 24 hour old broth culture, of which 0.000001 c.c. was fatal to control mice of *similar* weights.

SUMMARY *

	Separate Methods		Simultaneous Methods	
	Number of Tests	Percentage	Number of Tests	Percentage
Tests in which commercial serums failed to protect as many mice as noncommercial serums......	13	12	0	0
Tests in which commercial serums protected as many mice as noncommercial serums	72	68	4	36
Tests in which commercial serums protected more mice than noncommercial serums	21	20	7	64
Total tests..................	106	100	11	100

* This table does not include seven retests following rejection of serums on original tests.

In carrying out the test, two mice were given a dose of 0.2 c.c. of the culture, two mice 0.1 c.c., and one mouse 0.01 c.c., all previously or simultaneously inoculated with 0.2 c.c. of the serum.

PROTOCOL 1.—TESTS SHOWING IRREGULARITIES IN GROWTH OR VIRULENCE OF CULTURE

Serum, 0.2 C.c.	Cultures				
	0.2 C.c.		0.1 C.c.		0.01 C.c.
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A
A	36	36	S	S	S
1	24	36	S	S	S
2	S	S	S	S	S
3	S	S	S	S	S

No Serum	Cultures					
	0.0001 C.c.		0.00001 C.c.		0.000001 C.c.	
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B
	S	S	24	S	36	S

Throughout all the tests the doses of all serums used was 0.2 c.c. The culture used was grown for from eighteen to twenty-four hours in plain broth to which a few drops of the blood of an infected mouse was added. The hours of survival of the mice after injection are indicated in the protocols by a number, except survival for ninety-six hours or more, which is indicated by an S. It was found that survival for ninety-six hours was adequate for test purposes. A parenthesized number indicates the hours of survival of a mouse which was found to be infected with a contaminating organism, when sectioned.

PROTOCOL 2.—TESTS SHOWING IRREGULARITIES IN GROWTH *OR VIRULENCE OF CULTURE*

Serum, 0.2 C.c.	Cultures				
	0.2 C.c.		0.1 C.c.		0.01 C.c.
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A
A	30	S	72	S	S
1	72	S	72	S	S
2	20	40	48	30	S
3	24	72	S	S	S
4	12	20	72	S	S

No Serum	Cultures					
	0.0001 C.c.		0.00001 C.c.		0.000001 C.c.	
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B
	24	30	28	36	28	40

All mice were examined *postmortem*, to avoid the confusion of irregularities due *to death* by infection with extraneous organisms, the commonest of which is the bacillus of mouse typhoid.

It is not surprising that variations occur when we consider that a culture *which necessarily* varies in virulence and density must be employed. The most *striking* irregularity in the results of the tests is the survival of *one* or *both* of *the mice* receiving the larger dose of culture, while one or both of those inoculated with a smaller dose succumb.

PROTOCOL 3.—*TESTS* SHOWING IRREGULARITIES IN GROWTH OR VIRULENCE *OF CULTURE*

Serum, 0.2 C.c.	*Cultures*				
	0.2 C.c.		0.1 C.c.		0.01 C.c.
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A

IRREGULARITIES IN KILLING POWER OF CULTURE AND IN PROTECTION AFFORDED BY SERUM[1]

Protocols 1, 2 *and* 3 *indicate* the irregularities which occur in the growth or in the virulence of the culture. These tests were made each from a week to ten days later than the previous one, and the culture had been passed through one or more mice during the interval. They also indicate the irregularity of the protection afforded even by the same serum, A, at different tests.

---

[1] The lettered serums, A, B, etc., are those of producers not engaged in interstate sale of serum, and the numbered *serums*, 1, 2, 3, 4, are of those engaged in the interstate sale. *The* numbers refer to different specimens of serum in each test.

Protocols 4 and 5 are of tests made respectively one and three months later, and show similar irregularities in the protection afforded.

Among twenty-one series of tests it was found that Serum A failed eight times, or 38.1 per cent., to protect one mouse against 0.1 c.c. of the culture, and failed to protect either mouse five times, or 23.8 per cent.

PROTOCOL 5.—TESTS MADE THREE MONTHS LATER

Serum, 0.2 C.c.	Cultures					
	0.1 C.c.			0.01 C.c.		
	Mouse A	Mouse B	Mouse C	Mouse A	Mouse B	Mouse C
A	22	23	44	(52)	S	S
1	20	(55)	S	S	S	S
2	15	23	24	S	S	S
3	22	S	S	S	S	S
4	S	S	S	S	S	S

No Serum	Cultures							
	0.00001 C.c.		0.000001 C.c.		0.0000001 C.c.		0.00000001 C.c.	
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B
	28	28	34	34	40	39	33	47

As it was considered possible that the method of injecting the serum previous to the culture might be responsible for irregularities, the method of injecting simultaneously after mixing in the syringe was tried with the results shown in Protocols 6 and 7.

PROTOCOL 6.—TESTS MADE BY SIMULTANEOUS INJECTIONS AFTER MIXING IN SYRINGE

Serum 0.2 C.c.	Cultures					
	0.2 C.c.		0.1 C.c.		0.01 C.c.

4	(28)	S	34	S	S	

No Serum	Cultures					
	0.0001 C.c.		0.00001 C.c.		0.000001 C.c.	
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B
	30	30	21	30	34	36

Protocol 7 shows the rearrangement of the test as it has been carried out during the later tests. Three mice were put on each of two doses, 0.1 c.c. and 0.01 c.c. of the culture. This procedure was adopted, since for test purposes it was decided that the increment between the 0.1 and 0.2 c.c. doses was too small to be of practical value.

It is apparent from a survey of the Protocols 1 to 7 that there is little preference between serums produced by institutions engaged in the interstate sale of it and those which do not make the serum on a commercial basis.

That it may be appreciated that there is no inherent difficulty in the production of this serum on a commercial basis, a summary is presented.

From these results it would appear, further, that the method of testing adopted by the Hygienic Laboratory results in a greater percentage of failures of serums to pass satisfactorily, but that the irregularities are inherent in the test, and not due to slight modifications.

PROTOCOL 7.—TESTS AS REARRANGED

Serum 0.2 C.c.	Cultures						
	0.1 C.c.			0.01 C.c.			
	Mouse A	Mouse B	Mouse C	Mouse A	Mouse B	Mouse C

1	20	(55)	S	S	S	S	
2	15	23	24	S	S	S	
3	22	S	S	S	S	S	
4	S	S	S	S	S	S	

No Serum	Cultures							
	0.00001 C.c.		0.000001 C.c.		0.0000001 C.c.		0.00000001 C.c.	
	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B	Mouse A	Mouse B
	28	28	34	34	40	39	33	47

The lack of influence of preservative in the commercial serum was shown by the test recorded in Protocol 8 in which both preserved and nonpreserved serum of the same bleeding was used.

CONCLUSIONS

While it would seem that the mouse test is irregular in its results, it is believed that it affords in its present state a valuable measure of potency of antipneumococcic serum when properly controlled.

The serum now available in the market is of as high a potency as that produced by laboratories not engaged in the sale of this product.

A Morgue Nuisance.—The opening of a morgue and undertaking establishment in a residence district, to the depreciation of the value of neighboring property, it is held in the Michigan case of *Saier* v. *Joy*, L. R. A. 1918 A, 825, may be enjoined as a nuisance.

FEEDING IN HYPEREMESIS GRAVIDARUM

CHARLES S. BACON, Ph.B., M.D.
Professor of Obstetrics, University of Illinois College of Medicine, and Chicago Policlinic
CHICAGO

A review of the work done on the etiology of hyperemesis gravidarum shows that there is probably some kind of a toxic element in all cases which disturbs the vasomotor system and renders more sensitive the vomiting center. A neurotic factor is generally present as well as peripheral irritation from the uterus. The latter generally disappears when the uterus rises out of the pelvis. The vomiting is therefore of the reflex type. A toxic element that causes central vomiting may sometimes exist, but neither laboratory nor clinical proof has been adduced. Serious injuries to the liver or kidneys or other organs may result from starvation and acidosis. The danger to these organs resulting from inanition or toxemia or both can be fairly well estimated by the relation of the ammonia nitrogen to the total nitrogen. The determination must be made by methods that are really quantitative, preferably the Kjeldahl for the total nitrogen and the Folin test for the ammonia.

In treatment, therefore, the important thing is to feed the patient properly, beginning radical treatment early. Hospitalization and good nursing, and keeping the patient in bed, are necessary. On account of the great importance of the neurotic factor, suggestive therapeutics should be employed. At first nothing should be given by the mouth, not even water.

We have three methods of nonoral feeding at our disposal: the subcutaneous, the intravenous and the rectal, the relative efficiency and practicability of which must be considered. The practicability of a method includes its safety, its economy, the patient's freedom from pain, etc.

The principle that should guide us in nonoral feeding is to give all the necessary food elements if possible. If it is not possible to give a sufficient quantity of nitrogenous foods, we should give energy foods which save the tissues.

By the subcutaneous method, water, the salts, glucose, soluble vitamins and sedatives may be given. The method is not suited to the administration of alcohol, and is more painful than the rectal method, and should generally be replaced by the latter except in emergency cases.

By intravenous feeding, all substances may be administered that are given by the subcutaneous method. Woodyatt, Sansum and Wilder have shown the importance of regulating the velocity of the flow of the solution and have found that 0.85 gm. of glucose per kilogram and hour can be given without causing intolerance. At this rate about 40 gm. of glucose could be given every hour to a woman weighing 50 kg., and in six hours about 250 gm., which would give about 1,000 calories of energy. The method is valuable in emergency when available. It requires a special apparatus and technic and is hardly practicable for ordinary use.

Rectal feeding remains the most practicable and, when properly given, is efficient. By this method all essential food elements can be supplied, such as water, salts, glucose, amino-acids and vitamins. The deficiency in nitrogenous foods can be made up in part by giving an excess of glucose and by alcohol. Sedatives, especially sodium bromid, can be added as needed.

Because there is no digestion in the rectum or colon, no attempt should be made to give undigested proteins. Amino-acids and peptones dialyzed from artificially digested meat or milk may be given. Because sugar and starch digestion does not take place in the colon, carbohydrates should be given in the form of a monosaccharid, preferably glucose, which is absorbed without change. As the absorption of fats is doubtful, they should be omitted.

Solutions of vitamins from the pancreas or other sources should always be added if the feeding is to be continued for a considerable period of time. I am indebted to Prof. William A. Welker of the University of Illinois Medical School for this most important addition to the feeding in hyperemesis gravidarum. He has suggested the possibility that the toxic element in this affection may be a deficiency in vitamins caused by the increased demand of the rapidly growing embryo, and has suggested some experimental studies to discover the truth of this hypothesis. The fact that peripheral neuritis gravidarum frequently accompanies hyperemesis gravidarum is suggestive, as polyneuritis is the most important finding in beriberi, the type of disease due to deficiency in the accessory foods.

An energy food of great importance in rectal feeding is alcohol. According to the valuable studies of Neumann, alcohol is more readily utilized by the tissues than the other energy foods, carbohydrates and fats, even when these are present in large amounts, and its administration leads to the same economy of protein as the ordinary non-nitrogenous constituents of the dietary. As alcohol is more easily absorbed than glucose and as it helps to prevent fermentation in the colon, it proves of great value when given in proper amounts and concentration. If given in excessive quantities or too great concentration, it may be eliminated unchanged and may also injure cell tissue. If given in not more than a 5 per cent. solution and not to exceed 100 gm. a day, it is practically all consumed and harmless.

The great importance of calcium makes it desirable to add a calcium salt to the injection. The constant acidosis indicates the addition of sodium bicarbonate. To diminish the central reflexes, sodium bromid may be substituted for the basic salt sodium chlorid in sufficient amounts, generally from 3 to 4 gm. per liter (quart). There is no reason for giving a solution of salts of concentration to make an isotonic solution. It is probably better to restrict the salts to 7 per thousand.

The solution should be at body temperature. This cannot be secured by heating the solution in the irrigator can and letting it drop through an unwarmed tube. It is necessary to warm the tube near the distal end, that is, just before it is joined to the rectal tube. This can be done by means of hot sandbags. The rate of flow of one drop a second, giving 500 c.c. in two hours, is nearly always tolerated, if the rectum and colon have been properly prepared.

A large enema of at least 1 liter should be given every day to remove particles that continue to come down from the small intestine and also substances that may be excreted from the mucous membrane of the colon. This enema also should be a hypotonic solution, for example, 5 per thousand of sodium chlorid, in order that some water may be absorbed from it. A small amount of alcohol, 1 per cent., may be added in the hope that a small amount of nutriment may be supplied in this way.

The cleansing enema may be given early in the morning, at 7 or 8 a. m. Then the nutrient enemas would start at about 9 a. m., 2 p. m. and 7 p. m. Sometimes it will be found desirable to add 10 drops of tincture of opium to the evening enema.

The composition of the rectal feedings will have about the following proportions: glucose, 50; alcohol, 50; calcium chlorid, 0.3; sodium bicarbonate, 3; sodium chlorid or bromid, 4; vitamin, as much as is sufficient; distilled water, enough to make 1,000. From 300 to 500 gm. are to be given three times a day. This mixture has an energy value of about 550 calories. If 1,500 c.c. are given each day, the patient will receive 825 calories. In two or three days the retching stops, the thirst disappears, and the patient is in a fairly comfortable condition. The great nitrogen loss is stopped and the total nitrogen output in the urine is often reduced to 3 gm. in twenty-four hours. The ratio of the ammonia nitrogen to the total nitrogen also falls, although it may still remain more than 20 per cent.

It now becomes a difficult task to determine when stomach feeding may begin. As a rule, it is better to be cautious than hasty. The returning appetite of the patient and her confidence in herself is at times a guide. If the pregnancy is approaching the fourteenth week and the uterus is raising out of the pelvis, the mental change is often remarkably sudden. Likewise in markedly neurotic patients, the cures are often sudden. Lavage of the stomach is frequently very desirable before beginning oral feeding. The foods best taken are generally some forms of milk, such as peptonized milk, malted milk and buttermilk. Egg albumin is added early. Rectal feedings are discontinued gradually and not until the stomach feeding is reestablished. Even when the patient has recovered completely, she should be kept under control until the sixteenth or the eighteenth week, as discouraging relapses are not uncommon.

Management along the lines indicated promises success in practically all cases in which patients are treated before inanition becomes extreme. Even in extreme cases by the help of subcutaneous feeding, cures may be effected. The great difficulty is generally in obtaining and keeping control of the patient, largely because of outside influence. In a patient under control, the induction of abortion is practically never required.

2156 Sedgwick Street.

Utilization of Lobsters as Food.—Another of our great aquatic resources that has suffered from the failure or refusal of the states to be guided by the teachings of zoology is the lobster. If the states had given heed to the elementary needs of the lobster as proclaimed by Herrick, instead of shaping their course so as to conform with the interests of those who for years have been profiteering at public expense, they could have made the lobster a staple, moderate-priced food for all time, whereas it has become such a rare and expensive article that the food administration might very properly place an embargo on its use as a wholly unjustifiable extravagance. One alleviating circumstance is that through the adoption of a system of artificial rearing devised by the zoologist Mead, the lobster supply in the waters of Rhode Island has been maintained better than in any other state.—Dr. H. M. Smith, "Contributions of Zoology to Human Welfare," *Science*, March 29, 1918.

A STUDY OF FOUR HUNDRED POSTMORTEM WASSERMANN REACTIONS

SUPPLEMENTARY REPORT *

STUART GRAVES, M.D.
Acting Assistant Surgeon, United States Public Health Service
LOUISVILLE, KY.

The bibliography of the subject of postmortem Wassermann tests was covered in an article[1] published in 1916. No further study of the subject was published in 1917 by any one. In the first article the reasons for doing postmortem complement fixation tests for syphilis were discussed and the technic was described in detail. The results of 290 tests were analyzed and the following conclusions deduced:

1. Postmortem Wassermann reactions confirmed antemortem reactions in 95 per cent. of thirty-eight control cases. Positives were confirmed in serum six hours' postmortem and negatives in serum twenty-two hours postmortem.
2. In 90.4 per cent. of cases showing postmortem anatomic lesions of syphilis or presenting evidence of syphilis in their histories, the serums postmortem gave positive Wassermann reactions.
3. The fact that positive postmortem reactions appeared in thirty-eight cases, which did not present postmortem lesions or historic evidence of syphilis and in which death was due to acute infections, tuberculosis or malignant tumors, cannot be interpreted to mean that the reaction was caused by those diseases because, in the first place, the histories and necropsies in those cases were not nearly complete enough to rule out syphilis, and, in the second place, because serums from ninety-four patients who died of acute infections, tuberculosis or malignant tumors, examined under similar conditions, gave negative reactions.
4. Only 7 per cent. of 282 cases showed negative reactions in the presence of anatomic lesions (aneurysms) characteristic of syphilis.
5. The reactions conformed to the anatomic and historical evidence in 84 per cent. of the cases.
6. The fact that only eight, or 3 per cent., of the serums were anticomplementary indicates that the serums were in good condition.
7. The average percentage of specific reactions was almost as high postmortem as would be expected antemortem.
8. The positive reaction appeared in twice as many males as females, in three times as many negroes as whites, and in white females in only 4.3 per cent. of the cases examined.
9. The Wassermann reaction, performed on postmortem blood according to the methods followed in this investigation, is a reliable aid to the diagnosis of syphilis.

The original series of tests has been increased to 400, and the number of postmortem tests controlled with antemortem tests has been about doubled. They form a part of more than 6,000 tests done in the laboratory in the last three and a half years. These 400 tests have been studied and the results set forth in Table 1.

In the first series, we did not take into consideration in Class 3 bloods from which serums could not be separated or which were hemolyzed or otherwise unfit for use, but only those which, when used, proved anticomplementary. In the last series we considered all bloods taken and found unfit for use from any cause, although only three were anticomplementary. In the 6,000 Wassermann reactions, twenty-eight, or

---

* From the Pathological Laboratory of the University of Louisville Medical Department and of the Louisville City Hospital.

[1] Graves, Stuart: A Study of Two Hundred and Ninety Postmortem Wassermann Reactions, Jour. Immunol., 1916, 2, 53.

0.46 + per cent., have been found anticomplementary and thirty-five, or 0.58 + per cent., have been found hemolyzed, coagulated or otherwise *unfit for use.* Our original conclusion is therefore strengthened that, if the postmortem serum appears all right and does not prove anticomplementary, it is safe for use. Confidence in the general results is further based on the results in Classes 1 and 2, in which the reactions were as might be expected from the anatomic findings or histories in 304 cases, or 76 per cent. In only ten of 400 were negative reactions found to contrast with *apparent syphilitic anatomic* lesions or positive evidence of syphilis in the histories. *If we find 2.5 per cent.* of negative reactions in living patients known to have syphilic, shall we argue that therefore the reaction is of no value? In the first series, all the patients of this class had aneurysms. Of the three in this series, one patient presented no anatomic lesions of syphilis, but gave a vague history of a chancre ten years before, although his *antemortem Wassermann reaction was only +.* The second patient presented a coarsely lobulated, sclerosed *liver with fanlike fibrous adhesions. His postmortem* Wassermann reaction agreed with his *antemortem* negative reaction. The third case was that of another aneurysm. In this the postmortem reaction was ± and the antemortem reaction negative. In the analysis of these three cases, the anatomic and historic evidence is surely overbalanced by the practical agreement of the reactions before and after death. On first thought, it seems strange that in eight of ten cases in Class 4, each showed the presence of an aneurysm, but in twenty-five other cases of aneurysms the postmortem Wassermann reaction was positive.

TABLE 1.—RESULTS OF 400 POSTMORTEM TESTS

	First Series	Second Series	Total	Per Cent.
Class 1. Wassermann tests positive with apparent syphilitic anatomic lesions or positive evidence of syphilis in histories	76	28	104	26
Class 2. Wassermann tests negative with no apparent syphilitic anatomic lesions and no evidence of syphilis in histories	161	39	200	50
Class 3. Anticomplementary or otherwise *unfit for use*	8	14	22	5.5
Class 4. Wassermann tests negative with apparent syphilitic anatomic lesions or positive evidence of syphilis in histories	7	3	10	2.5
Class 5. Wassermann tests positive with *no apparent syphilitic* anatomic lesions and no evidence of syphilis in histories	38	26	64	16
	290	110	400	100

We now come to Class 5, embracing positive Wassermann reactions in cases that revealed no anatomic lesions that could be regarded as syphilitic and offered no positive evidence of *syphilis* in their histories. These have been classified as in the earlier article into three subdivisions.

Of the twenty-six cases in the second series in this class, five showed a ± reaction, two + and five ++, leaving only fourteen of 110 which showed positive +++ or ++++ reactions without evident anatomic or historic evidence of syphilis. Of the latter, three agree with antemortem Wassermann reactions, which is of greater importance than the apparently unwarranted positive reactions. This class has been analyzed in the first article and explained conclusively, it seems to us. Here we shall simply revise the table of race and sex, which speaks volumes to any one who has worked where negroes are numerous.

Against the reliability of the Wassermann test, both antemortem and postmortem, it has been argued that, because the reaction appears positive in cases in which *syphilis is not objective or historical* while various infectious lesions are obvious, these diseases must *bring about changes in the blood that* cause complement fixation. Would it *not* be more *logical* to conclude that deaths in these cases have resulted from the most common fatal diseases, such as pneumonia and tuberculosis, to say nothing of *violence, in* patients who were mostly ignorant or unfortunate, *or in* vicious colored persons who were simultaneously victims of *early or late or treated syphilis? If the* positive Wassermann reaction is to be attributed to pneumonia, or *tuberculosis,* or other *infectious lesions, or* to malignant tumors, because it appeared in patients who had died of those lesions, of what weight is that argument when it is shown that, of the 161 cases in this series which gave negative postmortem Wassermann reactions and, with the exception of the last two, presented no evidence of syphilis, *121* were negative in patients dying from the following diseases: lobar pneumonia, 34; pulmonary tuberculosis, 16; *lobular* pneumonia, 14; acute peritonitis, 13; acute nephritis, 6; carcinoma, 5; acute vegetative endocarditis, 4; generalized tuberculosis, 8; tuberculous enterocolitis, 2; pneumococcus meningitis, 2; streptococcus meningitis, 1; meningococcus meningitis, 1; empyema, 3; perihepatic abscess

TABLE 2.—CLASSIFICATION OF POSITIVE WASSERMANN TESTS WITH NO EVIDENCE OF SYPHILIS

A. Bodies sent by coroner *to laboratory for necropsy.* No history whatever. Examination often partially restricted to evident cause of death. No opportunity for antemortem physical examination.

Stabbed to *death* (*Wassermann* + and Wassermann ++ in two cases)	3
Cardiorenal (*Wassermann* + *in one case*)	3
Shot to death	2
Lobar pneumonia	2
Burned to death	1
Choked to death	1
Skull fractured	1
Generalized tu*berculosis*	1
Total	14

B. Patients admitted to hospital but coming to *necropsy* as coroner's cases *because* dying within twenty-four hours or *without obvious* cause. *Little* or no opportunity for *history* or physical examination.

Lobar pneumonia	4
Pulmonary tuberculosis	1
Generalized tuberculosis (Wassermann *only* +)	1
False elephantiasis of genitals	1
Burned *to death*	1
Stabbed to death	1
Traumatic *septicemia*	1
Shot to death	2
Acute *pericarditis*	1
Acute *meningitis*	3
Acute peritonitis	1
Typhoid	1
Total	18

C. Patients admitted *to hospital. Necropsy permission* from *next of kin or friends* or *municipal* authorities in cases *of patients* without relatives or friends.

Generalized tuberculosis	3
Lobar pneumonia (one only +)	2
Cardiorenal *(one only +)*	2
Acute appendicitis and peritonitis (only +)	1
Streptococcus meningitis (only ++)	1
Gangrene of intestine, intestinal obstruction	1
Acute pyelonephritis	1
Acute tubular nephritis (negro male, aged 20)	1
Shot *to death*	1
Carcinoma	1
Pulmonary tuberculosis	6
Lobular pneumonia	2
Ulcerative endocarditis	1
Strangulated hernia	1
Lymphoblastoma	2
Sclerosis of liver	1
Acute peritonitis	2
Hemorrhage following operation	1
Typhoid	1

* C. O. refers to coroner's cases in which persons died outside the hospital and were never admitted. C. H. refers to coroner's cases in which death occurred in the hospital. H refers to regularly admitted patients or cases in which there had been some opportunity to take a history or make a physical examination. In the first two classes there had been no such opportunity.

Of 378 reactions, 168, or 44 4-9 per cent. were positive. Of course it must be realized that these positive reactions were obtained in a charity hospital, and 73.1 per cent. were negroes. The distribution as to race and sex is shown in Table 4.

TABLE 4.—DISTRIBUTION OF POSITIVE SERUMS

	Male	Per Cent.	Female	Per Cent.	Total	Per Cent.

Perhaps the strongest evidence in favor of the reliability of the postmortem Wassermann reaction is found in the controlled cases. In the first series, only two flat discrepancies were found in thirty-seven cases, a confirming average of 95 per cent. We have reason to believe that these discrepancies were not the fault of the reaction. In thirty-one additional controlled cases, not a single discrepancy of this type has been found. On the other hand, there are several cases which show interesting confirmation. In one case (A 16-214) the reaction was ± on the blood taken three days antemortem. Postmortem, it was the same, although absolutely no connection between the two was known when the latter test was done. When the serums are examined and the tests read, they are identified by numbers only. The same patient had had a ++++ reaction followed by two doses of arsphenamin (salvarsan) and several injections of mercuric salicylate during his last six weeks. In another case (A 17-1) a ++++ reaction on a spinal fluid postmortem reaction followed a ++++ reaction on the blood antemortem. The necropsy showed gumma of the calvarium and meninges, in which the *Spirochaeta pallida* was demonstrated by the Levaditi method. Similar evidence could be multiplied. In sixty-eight control cases, then, only two contradictions are found, a confirming percentage of 97+. Any series of complement fixation tests, running over a period of three and a half years, with specimens submitted by a large number of different people under varying conditions, which offers a confirming percentage of more than 97, is surely reliable. A ++++ antemortem reaction confirmed a ++++ reaction sixty hours postmortem. The longest time postmortem after which a negative agreed with an antemortem negative in the same case was twenty-two hours.

Having proved in these two papers, as we believe, that Wassermann reactions on bloods taken and tested under the conditions described are reliable, we may ask, Of what value is a postmortem Wassermann reaction? It is of value, first, because it affords material help in the diagnosis of pathologic anatomy. Not even with such technic as devised by Warthin can one always decide with the microscope whether or not a given lesion had its origin in syphilis. It is impossible at the postmortem table to investigate the history of the unknown, latent syphilis or a fresh infection. If a serologic test will produce positive evidence, it frequently will solve a puzzling pathologic problem. Second, and possibly of greater importance, is the value of a reliable postmortem Wassermann reaction in medicolegal cases. Sometimes the question of syphilis is of far-reaching effect. It could conceivably be a deciding factor in the disposition of a large estate. Frequently, it arises in insurance cases.

It seems strange that a question of such importance has not been studied more. Only one other paper on the subject has been published in English. Leading textbooks on serology barely mention it. The prevailing opinion seems to have been that the postmortem Wassermann reaction was unreliable and without value. The opposite is proved in this investigation.

CONCLUSIONS

1. Postmortem reactions confirmed antemortem Wassermann reactions in 97 per cent. of sixty-eight controlled cases. A ++++ positive reaction, sixty hours postmortem, was confirmed by a ++++ antemortem in a case with anatomic and clinical evidence of syphilis. A negative Wassermann reaction on blood taken twenty-two hours postmortem was confirmed by a negative antemortem Wassermann reaction.

2. In 91.2 per cent. of cases showing anatomic lesions of syphilis and presenting evidence of syphilis in their histories, the serums postmortem gave positive Wassermann reactions.

3. The fact that only 2.5 per cent. of the serums were anticomplementary or otherwise unfit for use compares favorably with 1.14 per cent. similarly unfit in 6,000 antemortem specimens.

4. Only 2.6 per cent. of 378 cases showing anatomic evidence of syphilis gave negative Wassermann reactions.

5. The reactions conformed to the anatomic and historical evidence in 304 of 378 cases, or 80.4 per

cent., which is considerably lower than it would be if satisfactory histories and physical examinations were recorded in Class 5.

6. There is no logical reason for supposing that acute infections or malignant tumors cause positive Wassermann reactions.

7. The positive reaction appeared in 2.7 times as many negroes as whites, in 1.7 times as many males as females, and in only eleven white females, or 6.5 per cent.

8. The Wassermann reaction, made on postmortem blood according to the methods followed in this investigation, is practically as reliable a test for syphilis as when done antemortem, and is of great value in pathologic anatomy and in medicolegal cases.

THE AGGLUTINATION OF HUMAN RED BLOOD CORPUSCLES BY HORSE SERUM *

HERBERT U. WILLIAMS, M.D.
AND
HAROLD A. PATTERSON, M.D.
Professor of Pathology and Bacteriology, and Instructor in Bacteriology, respectively, University of Buffalo Department of Medicine
BUFFALO

This study seemed of interest to us because of the increasing use, frequently intravenous, of horse serum in large doses, chiefly in the form of curative serums for the infections. Agglutination of the red blood corpuscles of animals by the serum of animals of other species has been extensively studied, especially by Bordet. Some observers also allude to the agglutination of human red corpuscles by horse serum. We have tested nineteen specimens of serum and we have found that it frequently agglutinates human red corpuscles in the test tube.

Nine of these were normal horse serum, only one of them containing a preservative (phenol [carbolic acid] or a cresol). Ten were antistreptococcus serum, antidysentery serum, antipneumococcus serum or the like, purchased in the open market or issued by official laboratories, all presumably produced from the horse and usually containing a preservative. The specimens came from six different localities. Some of them were nearly a year old. We used some normal horse serums a few days after they had been taken from the animal.

We examined all serums for bacteria by streaking drops on agar slants, rejecting those that gave growths, with one exception. The latter was a serum that had been tested on a large number of blood specimens before its contamination was discovered. We have used the results in this case because they were entirely in accord with our other results, and the bacterial contamination was moderate. Neither the age of a serum nor the addition of a preservative seemed to influence agglutination. Some of the serums were tested with only two lots of blood corpuscles, others with more than thirty different specimens of blood. In all, samples of blood from about seventy-five different individuals were used. Some of these were tested with from five to seven different serums. Most of the samples were collected in 1 per cent. sodium citrate in physiologic sodium chlorid solution; all were centrifuged and washed three times.

Five tubes were used to test a given serum with one specimen of blood. They were so mixed that the tubes contained 1 c.c. of a 1 per cent. suspension of red cells in the sodium chlorid solution, and serum in the desired dilution. The final dilutions of serum used were 1:20, 1:50, 1:100 and 1:200. A control with no serum was kept in every case. The blood specimens were never more than forty-eight hours old, and usually were less than twenty-four hours old. After the blood cells and serum were mixed, the tubes were incubated at 36 C. for one hour, and then allowed to stand in the room for a few minutes. The results were estimated both by the appearance to the naked eye and by examination of drops under the microscope. It was observed that the longer the tubes stood after removal from the incubator to a lower temperature, the more distinct was the agglutination. Our readings were usually completed an hour after removal of the tubes from the incubator. The readings made with the naked eye, and those made under the microscope usually agreed well; but the microscope furnished somewhat the more delicate test. With strongly agglutinating serums, the red corpuscles settled into a firm mass that could be broken up with difficulty at the bottom of the tube. In such cases the microscope would show clumping of practically all the red corpuscles into large masses, of probably from twenty to a hundred or more cells in a clump. In other cases the clumps were smaller, and frequently there were many free cells between the clumps. Without exception, the intensity of agglutination was greatest in tubes in which the concentration of the serum in the mixture was highest.

RESULTS

Of the nineteen serums tested, twelve produced some agglutination of human red blood corpuscles in the test tube, while seven produced practically no agglutination, in dilutions of 1:20, the blood corpuscles being in 1 per cent. suspension, and the temperature not being exactly that of the body, but more or less below it.

The twelve positive serums agglutinated half or more of the samples of blood with which they were tested in 1:20 dilutions; and ten serums did the same in 1:50 dilutions.

Two serums agglutinated each two different specimens of blood in 1:200 dilutions; and one serum, in 1:500 dilution, showed slight but definite agglutination of each of two specimens of blood when the tubes had stood in the refrigerator over night. The last was an antimeningococcus serum, nine months old, smelling of phenol or a cresol, and sterile by culture test. Different specimens of blood cells showed considerable differences in the amount of agglutination when they were tested with the same serum. These differences, however, were distinctly less striking than those shown by different samples of serum with the same blood. It will be understood, of course, that the blood corpuscles in these test tube experiments were suspended in about 100 times as much fluid as when in normal blood, in order to demonstrate small amounts of agglutinin, if present.

Ottenberg,[1] working on isoagglutination in human beings, concluded that agglutination may fail to take place if the concentration of agglutinin in the serum is low, or if all the agglutinin is absorbed by an excess of red corpuscles. Using our most powerfully agglutinating serum (the antimeningococcus serum mentioned), with undiluted whole citrated blood, when a platinum loopful of blood was mixed with a loopful of the serum at room temperature, agglutination occurred at once and was nearly complete. When a loopful of serum diluted five times and several loopfuls of blood were used, well marked agglutination took place in from four to five minutes. It is doubtful, however, if such experiments imitate closely conditions in the living body.

Having noted in our tests that agglutination was usually most marked when the mixtures in the tubes

---

* Presented in abstract at the meeting of the American Association of Pathologists and Bacteriologists, March 29, 1918.

[1] Ottenberg, R.: Jour. Exper. Med., 1911, 13, 425.

were allowed to stand for some time at room temperature, we made our readings throughout with this fact in view, in the hope of better detecting small amounts of agglutinin. We varied our original test by keeping the serum and the 1 per cent. suspension of red corpuscles, and the mixtures of them after they were prepared, in a water bath at 37 C.; and a single dilution of the serum of 1 : 20 was used. Six serums that had previously been found to have little or no agglutinating power gave practically the same result as before. Of three serums that had shown decided agglutination by the original technic, two gave well marked agglutination in 1 : 20 dilution after one and one-half hours at a temperature of 37 C. In the third serum, which was the antimeningococcus serum mentioned already as having marked agglutinating power, the result was startling. In the 1 : 20 dilution, no agglutination was visible after six hours in the water bath at 37 C. but agglutination became marked after the same tube had stood at room temperature about half an hour. The possibility that temperature might be an important factor in such experiments was suggested to us by the experience of Rous and Robertson,[2] who state that in rabbits repeatedly transfused with rabbit blood, agglutinins may develop, but agglutination of the rabbit's red corpuscles appears only at temperatures below 35 or 36 C., a fact which was determined by observations outside the body.

VALUE OF THE EXPERIMENTS

There are probably other factors also that make the application of test tube experiments to the living body of uncertain significance. Furthermore, in those human cases in which the administration of serum may be practiced, there is usually a disturbance of some of the functions, especially of the circulation, and frequently an alteration of body temperature from normal. Our problem is therefore one of great complexity.

An enormous amount of work has been done in trying the effect of alien serums on living laboratory animals. Among a multitude of investigators, certain observers assert that the agglutinating action of an alien serum for red blood cells may be the cause of an animal's death; while others contend that death is probably due to other properties of the serum.[3]

As far as we have examined the evidence, it seems to us inconclusive. Some cases of death after transfusion from man to man have been reported, in which death was probably due to agglutination of the red blood corpuscles.[4]

Our own experiments on animals with injections of normal foreign blood serum have given results that were not convincing. We have also immunized guinea-pigs by successive injections of washed rabbit red blood cells. The serum of these guinea-pigs became agglutinative and hemolytic for rabbit red cells. Heating the serum destroyed its hemolytic but not its agglutinative power, in dilutions of about 1 : 500. Rabbits, on receiving the heated guinea-pig immune serum intravenously, in doses of from 4 to 8 c.c. per kilogram, died in a few hours or over night in about half the experiments. The dilatation of the right heart and of the veins in general, and the numerous masses of agglutinated red corpuscles found in the vessels, made a very striking picture. Decolorized red corpuscles and staining of the blood serum, however, together with a dark color in the urine, were also present, giving clear evidence that hemolysis had taken place. Therefore, like other observers, we have not been able to exclude the possible action of a toxic substance in our *experiments.*

One of our objects in reporting our observations is to give force to the suggestion that in human cases that result fatally, in which large injections of serum have been given, the possibility of agglutination of red corpuscles should be considered at necropsy; and in suitable cases blood examinations might be made during life. Also if normal horse serum or an immune serum is to be used in large doses, and especially by intravenous injection, a safe and simple precaution would be for the investigator to take a little of the horse's blood, just before the final bleeding, and test the serum for agglutinating power with a number of specimens of human blood, rejecting any horse whose serum had distinct agglutinating power. In the case of horses to be used for making immune serums, such a test would, of course, be performed before beginning immunization.

THE UREA INDEX AS A TEST FOR KIDNEY FUNCTION IN A WAR HOSPITAL *

REGINALD FITZ, M.D. (NEW YORK)
Captain, M. R. C., U. S. Army
FRANCE

During the past nine months, observations on nephritis have been made in this hospital, with McLean's[1] urea index as a test for kidney function. The results have been so helpful for diagnosis and prognosis that the technic employed and certain case protocols are recorded in order to show that the test can be carried out advantageously in a tent hospital with only elementary laboratory facilities.

McLean's directions were followed absolutely. Before each test the patient was given from 150 to 200 c.c. of water, to insure a free flow of urine. One half hour later, in order to start with the bladder empty, he voided. The time of voiding was recorded to within one minute. About thirty-six minutes later, at least 3 c.c. of blood were withdrawn from an arm vein into a dry tube containing a few milligrams of potassium oxalate to prevent clotting. At the end of seventy-two minutes from the first voiding, the bladder was again emptied, the urine carefully measured to within 1 c.c., and used for analysis. The patient took no food or water during this period. Otherwise no restrictions were placed on him. The seventy-two minute period was merely for convenience, as being one twentieth of twenty-four hours. Any other period, preferably not too long, would serve.

Analyses were made by the most accurate, convenient and rapid method available for determination of urea in the blood and urine. The urease method, introduced by Marshall,[2] fulfilled all of the requirements. This method depends on the breaking down of urea into ammonia and carbon dioxid by the specific enzyme found in the soy bean and the subsequent determination of the ammonia. The permanent preparation of urease described by Van Slyke and Cullen[3] was used, and determinations were carried out in the manner described by them, with a few necessary modifications. The method is simple, very rapid and requires the minimum of manipulation. Three analyses are necessary: blood urea, urine urea, and urine ammonia. The last is determined in order to correct the urea figure for preformed ammonia, which is also determined in the urea method. Since the method depends on the quantitative determination of ammonia by its aeration into weak acid and titration of the excess acid with alkali, it was necessary to use some sort of aeration apparatus. A water suction pump would have been satisfactory, but water was not always available. However, it was found that an ordinary chest aspirating pump produced sufficient vacuum to complete the reaction in about forty-five minutes.

[2] Marshall, E. K., Jr.: Jour. Biol. Chem., 1913, **14**, 283.

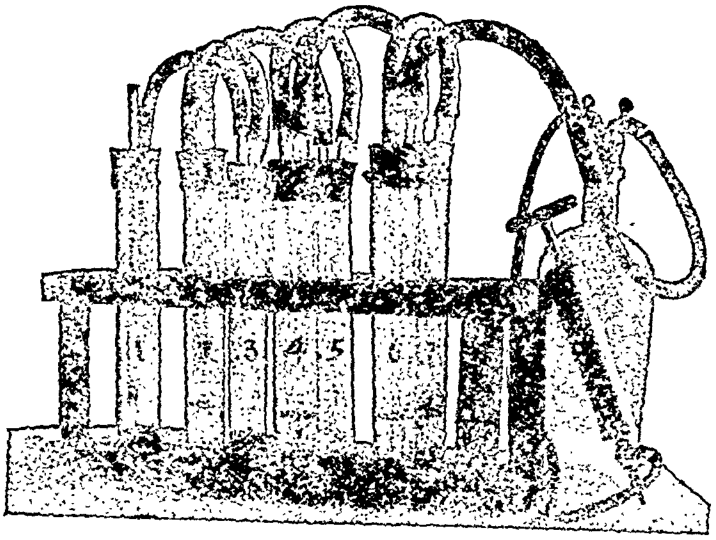

Fig. 1.—Apparatus for aeration of ammonia into fiftieth normal acid with chest aspirating pump: Tubes 1, 2, 4 and 6 contain fiftieth normal acid, Tube 1 being used to absorb whatever ammonia may be present in the air. Tube 3 contains urine only; Tube 5 contains urine and urease; Tube 7 contains blood and urease. The current of air is drawn through the tubes from 1 through 6 by means of the chest pump and vacuum bottle.

The acid and alkali used in titration are fiftieth normal and hundredth normal alkali and fiftieth normal acid. Such weak solutions tend to change if they are allowed to stand too long. To obviate this, normal solution were kept in tightly stoppered bottles from which a few cubic centimeters were frequently taken and diluted in calibrated flasks with the proper amount of distilled water. Every week or ten days the solutions were checked.

To carry out the test, therefore, the apparatus included burets for hundredth normal and fiftieth normal alkali, an aspirating set, and the few necessary reagents and the glassware. The equipment could be packed in a small box and set up anywhere in a few minutes. The entire time used for a test was only seventy-two minutes for the period and about seventy minutes for the completion of the analyses.

The results from the determination were calculated to the form in which they are to be expressed in McLean's formula. The weight of the individual should be known to within 1 kg. As scales were not always obtainable, the patient's weight was estimated and was assumed to remain constant during as many tests as were made. This introduced a slight but inevitable error. The four variables were substituted in the formula and the index calculated by McLean's special calculating device on a 10 inch slide rule.[4] With a little practice in reading the scales, calculation became mechanical and required only a few seconds. Without a slide rule, calculation could be performed by logarithms.

Perhaps the most striking case encountered to demonstrate the prognostic value of the test was the following:

Case 1.—*History.*—Private C. A. B., aged 24, admitted, Jan. 22, 1918, had been well all his life except for attacks of "nephritis" in 1915 and 1916. Despite this previous history, he had no difficulty in getting into the Army and was able to do his work satisfactorily. About the end of December, or a month before coming to the hospital, he began to notice that he became easily tired, having to fall out on marches, and getting short of breath on exertion. When he arrived in the hospital, he was comfortable, except for considerable dyspnea, and said that he felt as well as he had for several days.

Physical Examination.—His face was puffy and pale, though there was no demonstrable edema elsewhere. His heart was slightly enlarged to percussion, the action regular, not rapid, the sounds of good quality, a blowing systolic murmur was heard over the precordia, loudest at the base. The systolic blood pressure was 135 and the diastolic 45. There were no signs of peripheral arteriosclerosis nor eyeground changes. The lungs were negative except for numerous diffuse scattered râles in both sides of the chest without signs of consolidation or hydrothorax. The abdomen, genitals and extremities were negative. A casual specimen of urine contained a trace of albumin, was pale, of low gravity, and contained a few leukocytes and an occasional cast. Without functional studies, the patient gave the impression of having nephritis, not notably sicker than many others who had been admitted previously. Analysis, however, showed the blood urea to be 3.72 gm. per liter, and that the urea index was less than 1. These facts, discovered within two hours after the patient's admission, proved that the man was critically ill and made it seem probable that he would die within a short time. The subsequent course is shown graphically in Figure 2.

Course.—As can be seen, there was no oliguria until the last three days of life, the excretion of chlorid was not materially interfered with, there was no marked albuminuria, and there was a dropping blood pressure. During the first few days the patient appeared to be improving. Thus from clinical and routine laboratory observation alone, it would have been impossible to recognize the seriousness of the patient's condition. However, a second urea index three days

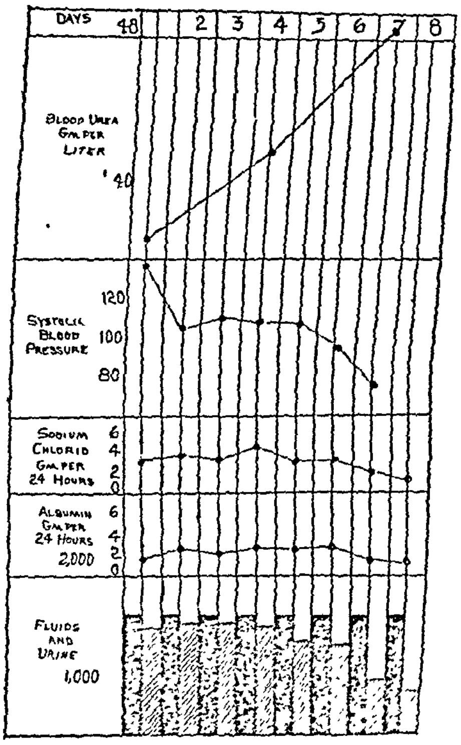

Fig. 2.—Renal function in Case 1.

---

[3] Van Slyke, D. D., and Cullen, G. E.: Jour. Biol. Chem., 1914, **19**, 211.

[4] The rule, with directions for use, may be obtained from the Keuffel and Esser Company, 127 Fulton Street, New York.

after entry showed that the index was again less than 1, and that the blood urea concentration had climbed to 4.15 gm. per liter. Three days later the patient became oliguric, the blood urea rose still farther, and the patient died. At necropsy the kidneys showed a typical chronic glomerular nephritis with extreme atrophy of both kidneys, especially of the left, which weighed only 50 gm.

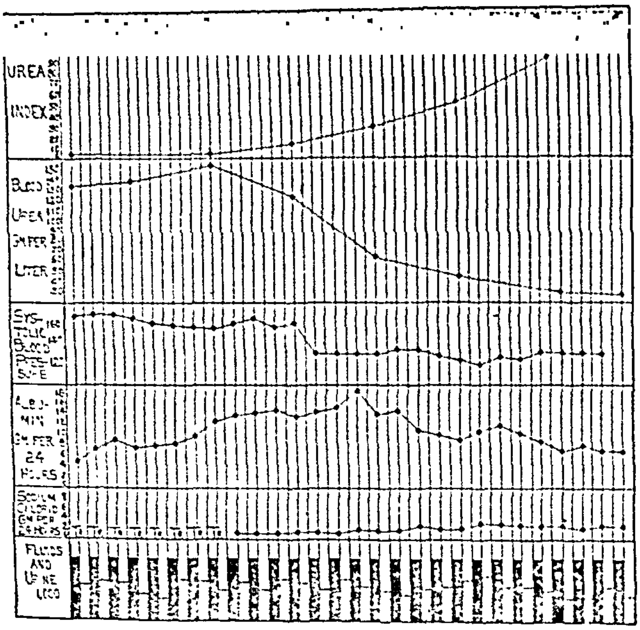

Fig. 3.—Renal function in Case 2.

Two other less serious cases are recorded to show the satisfactory fashion in which the course of an acute nephritis can be followed by this test, and the results of slight modifications in treatment.

Case 2.—*History.*—Private G. B., aged 40, admitted, Sept. 19, 1917, had been well until seven days before entry (September 12), when he suddenly felt headache and general malaise, soon followed by shortness of breath and the development of generalized edema. Despite these symptoms, he carried on until two days before entry (September 17).

Physical Examination.—The man was orthopneic, with marked edema of the face, sacrum and legs. There was no hydrothorax or ascites. The heart was not enlarged, the action was regular, not rapid, and the sounds were normal. The systolic blood pressure was 166 and the diastolic 80. The lungs were normal except for a diffuse bronchitis without signs of consolidation. The abdomen was normal, as were the eyegrounds. The observations made on renal function are shown in Figure 3.

Course.—As can be seen, during the month that the patient remained in the hospital, he had a persistent oliguria so that his edema, by actual weight, increased. For the first fifteen days, the excretion of albumin rose, and for the first twelve days, the blood pressure remained almost constantly elevated. From this evidence alone, it would have seemed that the patient was making little if any progress. The blood urea and urea index, however, gave valuable additional information. During the first eight days, the blood urea rose from 1.3 gm. per liter to 1.5 gm. per liter, and the index stayed below 10. These facts pointed to a severe nephritis, which was possibly increasing. After this, the blood urea fell rapidly to normal and the index rose, both beginning to change before the excretion of albumin had reached its highest figure and before the blood pressure had dropped. These findings showed that the patient was beginning to improve before there was any clinical evidence of it. The patient was evacuated with normal blood urea and urea index, though there still was massive edema. It seemed safe to predict that the patient would gradually improve and that eventually "dechloruriaation" and polyuria with loss of edema would occur. A letter written two months later by the patient's medical officer at home proved that such was the case.

Case 3.—*History.*—Private W. F. C., aged 34, admitted, Jan. 21, 1918, had noticed during the previous year that he had passed more urine at night than by day, but had felt well and able to work. About three weeks before entry (January 1), he became increasingly short of breath, began to complain of headache, and to develop edema in his face and ankles. At entry he was comfortable. His heart was not enlarged and was negative except for a faint systolic murmur over the precordia. The systolic blood pressure was 200, the diastolic 90.

Physical Examination.—The lungs and abdomen were negative. There was marked brawny edema on the face, legs and entire body. The eyegrounds showed slight vascular changes and one hemorrhage, which cleared up in about six weeks.

Course.—For the first twenty-four days the patient showed no frank diuresis, although the water output seemed to be gradually increasing. The excretion of albumin rose steadily and the blood pressure remained between 180 and 200. Thus, here again, from routine examination the patient seemed to improve very little. However, the blood urea fell gradually but consistently, and the urea index rose. It was safe to believe, therefore, that the condition was improving satisfactorily. Finally there was a diuresis accompanied by increased chlorid output and disappearance of edema. At

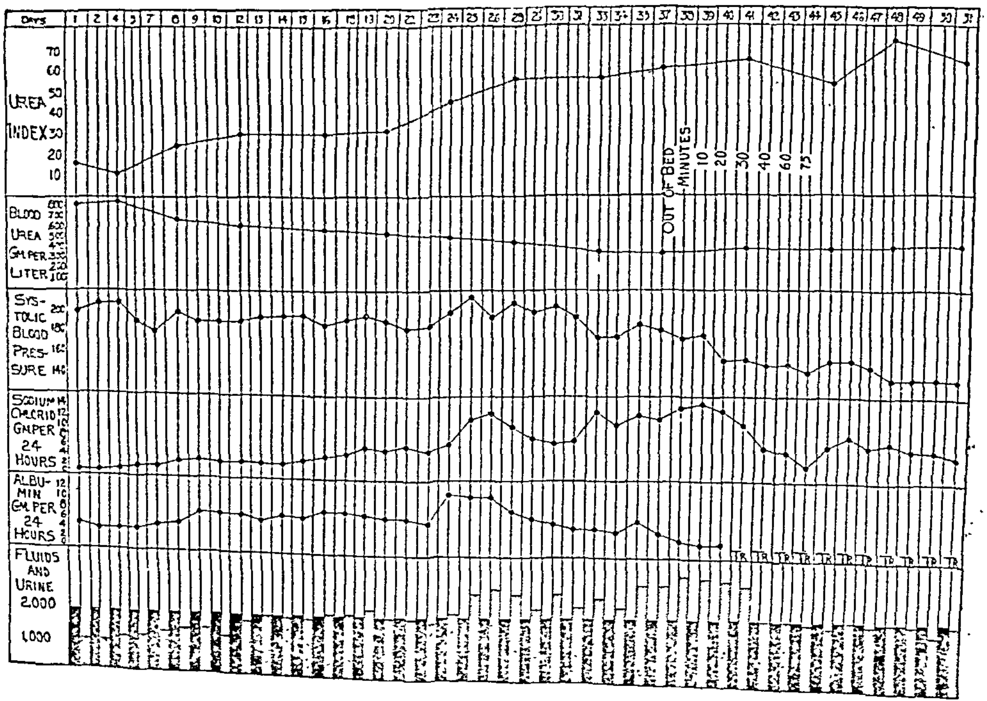

Fig. 4.—Renal function in Case 3.

about the same time, the albuminuria diminished and the blood pressure began to fall. The man seemed so much better that he was allowed up for increasing lengths of time after being in bed for thirty-nine days. There seemed to be no immediate effect. On the day after he had been up for seventy-five minutes, however, the urea index was definitely lower than it had been before, and because of this he was kept in bed once more. Three days later the index had risen again. It was concluded from this observation that further rest in bed was indicated, and that actual harm had been done in attempting to get the patient up too rapidly.

COMMENT

These examples are sufficient to show that the urea index test for renal function can be applied satisfactorily in a tent hospital with little if any laboratory facilities. A legitimate question is whether it has any advantages over the phenolsulphonephthalein test of Rowntree and Geraghty[5] under such conditions. As McLean has shown, the curves of percentage of phenolsulphonephthalein excreted in two hours and of the urea index are parallel and are quite striking. In certain respects the phenolsulphonephthalein test is the simpler. It seemed, however, that for field work phenolsulphonephthalein had one serious disadvantage. Phenolsulphonephthalein is a nontoxic dye substance which must be injected either intravenously or intramuscularly. While this procedure is never troublesome where asepsis is certain, under field conditions it is preferable to use intramuscular or intravenous treatment as little as possible. Moreover, patients do not like to be injected every day or two with a foreign substance which leaves even a slight local reaction. The urea index, on the other hand, requires only 3 c.c. of blood, which can be taken with a fine needle so simply that no patient will mind several bleedings in one day, and the test does not require any foreign body. For these reasons the urea index seemed the more satisfactory method.

On the whole, it becomes evident from the cases reported that the urea index is a feasible test for kidney function in a war hospital without particular laboratory facilities. As McLean has said, the method is applicable in a wide range of cases, easy of performance, and gives results that prove of practical value in the recognition, prognosis and treatment of certain conditions associated with impairment of renal function.

Mortality of Childhood.—In a reprint from the quarterly publication of the American Statistical Association for March, 1918, Louis I. Dublin, statistician of the Metropolitan Life Insurance Company, tabulates and analyzes the number of deaths and causes of death in the different age periods from birth to the age of 15 as shown by the returns from the registration area, and draws conclusions and recommendations as to the reduction of the death rates for the period between the ages named. He says there is opportunity and need for concentrating the efforts of the public health movement on the further reduction of child mortality. The reduction already accomplished shows large possibilities for conservation of life. The preschool years of childhood have as yet received little attention from the life conservation movement however, public health programs having more to do with the children after they enter school. The extension of infant welfare stations and clinics is suggested. An important consideration is improvement in our sources of information on child life, through accurate census-taking, improved birth registration, and a greater exactness in death registration.

THE STREPTOCOCCUS EPIDEMIC AT CAMP ZACHARY TAYLOR, KY.

A SURVEY *

HERBERT FOX, M.D. (Philadelphia)
Major, M. R. C., U. S. Army
AND
WALTER W. HAMBURGER, M.D. (Chicago)
Major, M. R. C., U. S. Army
CAMP ZACHARY TAYLOR, LOUISVILLE, KY.

It was expected that the acute respiratory diseases would share with meningitis the responsibility for the morbidity and mortality of the Army camps. It was, however, the pneumococcus from which it was thought the greatest number of infections would come, so that the history of the acute infections of Camp Zachary Taylor was as surprising as it was interesting. Pneumonia in its lobar form, due to the pneumococcus, appeared early in the autumn months and has continued at the rate of about fifty cases a month ever since, a summary of which is given in the accompanying tabulation.

DETERMINATION OF PNEUMOCOCCI

	No.
Type I	37
Type II	29
Type II a	6
Type III	0
Type IV	93

The field was soon occupied by the streptococcus, which did not confine itself to the respiratory tract, but extended its malign influence to practically every tissue of the body, appearing, indeed, in the form of an epidemic infective agent. Chronologically, measles appeared after the pneumococcic pneumonias, typical in character, moderate in severity and leading to a few deaths, the number being the usual for the adult. The cause of death was bronchopneumonia, generally distributed through the lungs, and of the character usually associated with measles. A report on the pathology of all these infections has been submitted by Lieutenant Lucke. It is noteworthy that there was an insignificant number of cases of scarlet fever and chickenpox, and no cases of whooping cough.

On the appearance of the great wave of the streptococcus infections, late in November, the clinical picture and pathology changed noticeably. The men became ill very rapidly, were completely prostrated, and gave the appearance of having a profound toxemia; empyema began to appear; pathologically, the lesions turned from catarrhal to hemorrhagic, and the anatomic evidences of septicemia were manifested. At the same time also there began to appear severe angina, tonsillitis, otitis media et interna, and mastoid abscess, followed in several instances by meningitis. There were also some cases of erysipelas, and streptococcus cellulitis from one or another local cause.

By this time we were well aware of the presence of this streptococcus epidemic, and looked at it as separate and distinct from the measles. We based this view on the multiplicity of lesions caused by it, which stood in no relation to measles, and on the change in the pathology of measles itself as seen at the necropsy table. That the measles may have been increased in severity by the presence of a streptococcus is undoubted, but we believe that the two epidemics existed as separate entities. This is further strengthened by the history in the late winter, as measles subsides while the streptococcus even increases its virulence with the production of primary sepsis and serositis, frequently ignoring the lungs and giving a high mortality.

---

ORIGIN OF THE INFECTION

Searching for the explanation of this infection, it seems most probable that it is a local process in some and a primary septicemia in other cases. Early in the history of the infection there were clinical reports of initial bronchitis, and evidences of pneumonia. In these the spread to the pleura may have been lymphogenic or peribronchial, as McCallum has suggested, the later sepsis being in these instances due to spread through the blood stream. In the recent cases, however, it would seem more likely that the process was a primary septicemia, although the infection atrium is clear in no case. The cases of primary empyema must surely be due to hematogenic spread, because, first, there was no pneumonitis in five of them; secondly, there was no cervical cellulitis and lymphadenitis with extension into the thorax, and thirdly, streptococcemia existed. There was also a case of primary pericarditis.

As the epidemic is reviewed, the gradual and sustained rise of virulence is noteworthy and requires an explanation. It seems desirable to mention that the autumn of 1917 at Camp Zachary Taylor was made unpleasant for the soldiers by considerable wind and dust; the latter was quite irritating and occasioned considerable coughing. The ground here is of clay and sand and has been highly cultivated. This may have contributed to the origin of the infection. A large percentage of soldiers at Camp Zachary Taylor are from rural or small town districts, and it is in such men that the infection has taken the greatest hold. It seems that the streptococcus has experienced a rise of virulence by ever appearing increments of newly exposed individuals.

When men arrive at the camp, some are in the incubation period of communicable disease, some are feeling the effects of the use or abuse of their last fling of freedom, and some bring infective organisms with them. For example, it was found that 15 per cent. of one contingent, mixed rural and urban, arrived at camp carrying hemolytic streptococci in the pharynx. Whether or not the draft men arrive depressed in vital resistance, by one cause or another, the first period of their life here is new to them and they are subjected to unaccustomed conditions, exercise, excitement, and exposure both to the elements and to infective agents. This results in fatigue, insomnia, and general depression of resistance until they have taken their bearings. With such an opportunity it seems that everything favors an increase in virulence of any organism that may be passing about, the effect being the same as the exaltation of virulence obtained by passing an organism through a series of animals in the laboratory. The movements of men in the camp, at Y. M. C. A. buildings, theaters, mess halls and barracks offer an excellent opportunity for the transmission of infection. The picture is sharpened by a consideration of the lack of knowledge of personal hygiene on the part of many men, especially in the depot brigade, before they have had sufficient instruction from the officers. They hawk, cough, sneeze and blow the nose without protecting the face, thus spreading the infection by droplets. When they get into the camp proper they meet new men heavily infected with streptococci, because it has been shown that the organism is to be found in all organizations. In one company of men, at camp an average of six months, 83 per cent. carried hemolytic streptococci in the pharynx. Another factor that assists in enhancing the virulence of the bacterium is a delay in early diagnosis of an illness, either because the man himself does not know he is a menace, or because he is not inspected sufficiently often. One reason certainly is that it is left to the soldiers to report themselves at sick call, whereas the medical man should go after the soldiers to weed out communicable diseases early. When soldiers crowd in the infirmaries for sick call, those with incubating infections contaminate those about them.

While, from the foregoing, it is evident that we consider the camp as an incubator of this streptococcus infection, it is nevertheless true that attempts should be made to prevent the men coming to it with an acute disease under way. A task that might be taken by the local exemption boards is that an inspection of the draft could be made at their station of departure, that is, before they board the trains and expose their fellow travelers to the camp.

METHOD OF COMBATING THE EPIDEMIC

Our attack on this epidemic entailed the following procedures:

The isolation of all measles patients entering the hospital, shown by blood-agar plates to have hemolytic streptococci in the pharynx, from those free from the organism. It has been shown by Alexander and Levy that the complications of measles are directly connected with the presence of streptococci in the pharynx, and that the isolation of such clean cases materially reduces hospitalization. All measles patients are swabbed in an observation ward.

The examination of dust from recreation rooms and certain barracks demonstrated streptococci. Proper policing of floors washed with disinfectants slightly reduced the morbidity.

It was suggested that whenever several streptococcic cases appear in a company, the whole personnel should be swabbed and the carriers isolated. This was found impracticable, because the barracks did not lend themselves to such arrangements, and military training would be greatly disarranged.

All patients with infectious diseases are put in wards arranged on the cubicle system with sheets, and all persons walking around or coming into the ward are masked.

Experimentation has been undertaken with several solutions of seemingly practical character to destroy streptococci on the pharyngeal wall. These have been unsuccessful so far. Several carriers who have failed to clear up with the use of various solutions in the ward, have promptly done so after being placed out on the porches with abundance of fresh air, good food and exercise.

It has further been proposed that all incoming individuals be swabbed for the presence of streptococci, and those harboring them isolated from the carriers. This has thus far been impracticable because of the absence of suitable small isolation units.

Because of the low resistance of the human being to the streptococcus when it once gets started, it seems that protective vaccination might offer some advantage, even though animal experimentation has not, in the past, demonstrated that serviceable antibodies in any considerable quantity are developed in the lower animals. This does not indicate that a cellular immunity might not occur if these organisms were used in the vaccine. It is certain that a clinical experiment of this sort with a personal record of the soldier so immunized would be the only answer to the question.

In addition to the foregoing, a detention camp in which men may rest and become acclimatized is imperative, and it should be arranged in small units, so that measles immune and nonimmune, streptococcus carriers and noncarriers or suspects of any kind may be quarantined for three weeks. Visitors should be prohibited; indeed, the isolation should be complete, with attention at all times to amusements and instruction, to prevent the men becoming restive.

When men report at infirmaries they should be separated while awaiting attention, and masked if coughing or complaining of a sore throat. The wards should be divided by sheets into cubicles, and general measures used to prevent crossed infections. All patients coming to the base hospital are masked, and on arriving at the receiving ward are given a cursory examination to find out into which one of the arranged cubicles they are to be put to be further examined and await their transfer to a ward. All wards for infective cases are arranged in cubicles, and all ambulant persons in the ward and all visitors are masked and gowned.

The use of masks in wards and latrines is similar to the method installed at Camp Grant by Major Capps.

CONCLUSION

The study of an epidemic of streptococcal infections in Army camps shows it to be a comprehensive problem of many interrelated parts, each of which should be analyzed and controlled. The local exemption boards may be regarded as multiple foci of potential disease feeding into the camp; the depot brigade as the portal of entry of men and infection into the camp, and the regimental infirmaries as the outpatient department of the base hospital.

A STUDY IN WAR NEPHRITIS

A NEW CONDITION ASSOCIATED WITH HEMORRHAGES IN THE BLADDER WALL AND URINARY SYMPTOMS: PRELIMINARY REPORT *

JOHN P. PETERS, Jr., M.D. (New York)
Captain, M. R. C., U. S. Army
AND
A. RAYMOND STEVENS, M.D. (New York)
Captain, M. R. C., U. S. Army
FRANCE

Any review of the literature on war nephritis leaves one with the feeling that the subject lacks definition. There seem to be but two possible interpretations of the great variance of views and conclusions that appear: the first, that no single clinical entity is sufficiently inclusive to explain them all; the second, and more radical, that there is no such distinctive disease as "war nephritis."

It was from the latter point of view that we decided to approach the subject: we wished first to learn whether such a distinctive disease as war nephritis existed, and, if so, how to distinguish it from other varieties of acute nephritis. It was impossible to attack the problem from all sides at once, and we therefore restricted our preliminary work almost entirely to the careful clinical observation of every patient with nephritis, albuminuria and hematuria that came into the hospital. Practically we were only looking for a lead, hoping to find a loose end by means of which we might help to unravel the tangle.

Up to date, 155 cases have been studied. The amount of work done in each instance depended entirely on the nature of the case. We have found, among other things, an apparently undescribed condition that may prove to be a clinical entity. This paper is intended as a preliminary report of this condition, on which we are continuing our studies as fast as the limited amount of the material allows.

Of the 155 patients examined, seventy-three, or 47 per cent., were found to be suffering from chronic cardiac or renal disease with a recurrence of symptoms. In eight of these cases the first attack had occurred at the front; these may be called "recurrent war nephritis." Fifty-eight gave pretty clear evidence of previous cardiac or renal disease in history, physical signs of course. Seven gave no history of previous cardiac or renal symptoms, but suggested in their course an underlying chronic affection. This whole group represents largely the inadequacy of our methods of estimating normality. The relatively high number of cases of recurrent war nephritis (eight, or 5 per cent.) would seem to indicate that men who have suffered from this condition are unfitted for active duty in the front area. All these men had been returned cured after several months' treatment.

Of the remaining eighty-two cases, forty-nine presented a syndrome which marked them definitely as acute nephritis. Some of them were indistinguishable from similar cases seen in civil practice. Others differed in the relative importance of certain symptoms. The distinctive features of these cases have been brought out by Sir John Rose Bradford,[1] and, more recently, by Dunn and McNee.[2] We have nothing to add to their able descriptions of war nephritis proper.

A small group of eight patients developed signs of nephritis in the course of what appeared to be typical trench fever. In four of these the nephritis appeared as a transient albuminuria with casts, which rapidly cleared up. Five had hematuria as well, two had dyspnea and two edema. In only two cases was the course prolonged, and in those two, albumin and casts were still found in the urine after two months' treatment. Whether or not the trench fever bore any causal relation to the nephritis we are unable to say; but the occurrence of renal complications in these cases leaves one with the impression that the hitherto accepted view of the absence of after-effects from trench fever is not entirely satisfactory.

Four cases of panurinary infection were found. All were febrile cases with pyuria, and in all the presence of a cystitis and double bilateral renal infection was demonstrated by means of cystoscopy and ureteral catheterization. From the urines of which cultures were made the colon bacillus was obtained.

Early in the course of the work we received a patient with profuse hematuria who complained of symptoms strongly suggesting vesical calculus or papilloma. Cystoscopic examination by one of us revealed neither stone nor neoplasm, but, instead, multiple submucous hemorrhages in the bladder wall and blood pouring from both ureters. Since then we have found fourteen other patients with the same bladder picture, and latterly have been able, in several

[1] Bradford, J. R.: Quart. Jour. Med., 1916, 9, 125; Jour. Royal Army Med. Corps, October, 1916.

[2] Dunn and McNee: Brit. Med. Jour., 1917, 2, 745.

instances, to anticipate the condition we should find, before performing cystoscopy. These fifteen cases make up 10 per cent. of all the nephritics received during the course of this study, and 15 per cent. of all the acute nephritics, proportions that render the condition of more than passing importance.

The clinical picture presented by these patients, if they are considered as a group, was entirely different from that of ordinary acute nephritis. The predominant symptoms, and the only constant ones, were profuse hematuria, frequency of urination and urgency, and pyrexia of an irregular and variable type. The majority also had pain on urination. In a few cases a diagnosis of renal calculus had been made, on account of the association of renal colic and hematuria. These patients later suffered from difficulty in starting the urinary stream, and from severe suprapubic and urethral pain. Cystoscopy revealed the presence of the typical vesical lesions, and in four cases in which the operation was performed while the patients still showed gross hematuria, blood was seen emerging from both ureters. The colicky pains have in every case been coterminal with the gross hematuria, and may have been due to the passage of clots which, in some cases, were later found in the urine. The frequency and dysuria often persisted after the urine had completely cleared up.

Only one of these patients was afebrile throughout the course of the disease. In most cases the initial temperature was quite high, and in one instance 103.8 while under our observation. Of course our records are incomplete, because we have scant notes on the initial period of the disease. The temperature curve is very irregular, and no definite type appears. However, there seems to be a tendency toward slight relapses after the first remission.

RESULTS OF EXAMINATIONS

History of Previous Illnesses.—One patient had had scarlet fever without complications in 1915. Another had diphtheria twenty-six years ago, and rheumatism nine years later. One had been subject to tonsillitis. Three said that they had suffered from some shortness of breath on long marches, but had had no other symptoms of cardiac disease. One had had edema of the face and limbs two years before, which was ascribed to poisoning. Two patients had had gonorrhea; the remainder denied venereal diseases, and none showed any evidences of existing gonorrhea or syphilis. Two had been rejected for the Army, one in 1915 and the other in 1916, but did not know why. One of these had a marked myopia. All were members of active line organizations except one, an orderly of this hospital who had passed a careful physical examination before admission to the Army. Their ages ranged from 19 to 36. All had been in France for at least four months, and all except the orderly mentioned above were in the front area at the time of onset of the illness. With the possible exception of the one patient who had had general edema, then, the cardiac and renal histories may be considered negative.

Mode of Onset and Prodromes.—In nine of the fourteen patients the onset was sudden, with hematuria and its concomitant symptoms. One said he had "felt queer" for twelve hours before the hematuria began. One, after a severe cough of seven days' duration, suddenly developed hematuria, urgency and dysuria. One complained of increasing weakness for six days before the onset of urinary symptoms. (As this patient failed to recognize a gross hematuria, even after he had burning urination and frequency, it is possible that he may have passed blood earlier.) Another had headache, nausea and vomiting for two or three weeks before the appearance of urinary symptoms. Seven complained of weakness or giddiness at the time of onset, and one of these fainted twice. Eleven had headache. Ten had pains in the small of the back, sometimes resembling renal colic. A considerable number also complained of pains in the legs. Four vomited, and one had diarrhea for twenty-four hours only. Two besides the patient mentioned above complained of cough. Two of the three cases in which temperature records were obtained showed a pyrexia within twenty-four hours of the first appearance of urinary symptoms.

Two cases have not been included in the previous discussion for reasons that will appear, and will be considered separately later.

Physical Examination and Clinical Findings.—Those patients who were admitted during the febrile stage of the illness approached, in general appearance, the picture of an acute infection; later the most striking features were pallor and general debility. Unfortunately we were unable to determine the actual degree of anemia except in one case. In this, both red cells and hemoglobin were reduced about 40 per cent. Three of the cases showed herpes labialis, and in one instance the lesions later became infected. With these exceptions the skin and visible mucous membranes were clear, but for the usual pediculosis and scratch marks. Cutaneous, oral and conjunctival hemorrhages were never found, in spite of repeated examinations. Edema and dyspnea were noticeably inconspicuous. Puffiness of the face was observed once and reported once in the history; the former patient was also reported to have had slight swelling of the legs at the onset of his illness. Exertional dyspnea was not common, and occurred only in association with pyrexia. With one exception no signs of respiratory disease were discovered. This patient had had a severe cough, antedating his urinary symptoms by ten days. On admission the cough was subsiding, but râles, dulness and increased voice and breath sounds were present over the right upper lobe. Abnormal cardiac signs were discovered in four cases: One showed a transient enlargement of the area of cardiac dulness without murmurs; two, systolic murmurs without enlargement, and one, a slight persistent enlargement with a transient systolic murmur. There were no disorders of cardiac action. The spleen was palpable in one instance. The liver was never found enlarged either by palpation or by percussion. Tenderness in the upper abdomen was present in two cases, and tenderness in one or both costovertebral angles in five. In spite of the frequency of pains in the legs, tenderness in the shins and calves was present only once, and then was very slight.

Special Examinations and Laboratory Findings.—Repeated blood pressure examinations were made by the auscultatory method with the Tycos apparatus. The tension was never found elevated, reaching 140 as a maximum in only a single observation. Ophthalmoscopic examinations in eight cases revealed no hemorrhages nor other abnormalities. Of seven blood cultures, only two showed any growth. In both of these, single colonies of cocci (probably pneumococci) were found. It is safer to consider these as contaminations, for the present at least, as subsequent cultures from the same subjects proved negative. From the catheterized bladder urine in eight cases, staphylococci, obviously contaminating organisms, were obtained in culture three times; the other specimens were found sterile. The following mediums were used: broth, glucose agar, hydrocele-glucose-agar and blood agar. In two cases, anaerobic cultures were also set up.

White blood cells and differential counts on six patients showed so little uniformity that no conclusions can be drawn from them. A red cell count and hemoglobin estimation on one patient showed 2,700,000 cells with 60 per cent. hemoglobin, a considerable anemia. No morphologic changes were observed in the cells except some central pallor. No nucleated red cells were found.

All the patients exhibited gross hematuria, of variable duration, in the early stages of the condition. All but one showed casts at some time. Usually the casts were of the hyaline and granular types; but frequently epithelial and red blood cell casts were present. Although gross blood did not persist very long, erythrocytes were observed in the urine as late as the fifty-ninth day of the disease in one case, and the forty-first day in another. Only once was any considerable number of leukocytes seen, and never frank pus. Sometimes the urine became negative for a period, with a later recurrence of albumin and casts. Albumin was seldom very marked; in most cases it could be fully explained by the amount of blood present. Only one patient was discharged with consistently negative urinary findings; and another, who is still in the hospital, has now had a negative urine for ten days. The majority left the hospital with a slight trace of albumin and a few casts; six showed blood cells persistently. The periods of observation varied from the eleventh day of the disease to the seventy-second. Although we have tried to follow these cases by means of cards, we have as yet received no replies.

The only renal function test which we have been able to employ is the phenolsulphonephthalein test. In all but three cases there has been a definite diminution in the excretion of the dye, the output varying from 15 to 48 per cent. in two hours. When repeated tests have been made, an improvement of function has usually occurred with convalescence.

Cystoscopy.—Cystoscopic examination of the earlier cases was undertaken to determine the origin of unexplained hematuria associated with symptoms pointing to lesions of the lower urinary tract. A striking and unusual picture was found: multiple hemorrhages in the bladder mucosa, unassociated with inflammation, tumor or stone. In those patients presenting gross hematuria at the time of cystoscopy, bloody urine was seen coming from both ureteral orifices. Renal tuberculosis and neoplasm were thought of, but seemed unlikely in view of the symptoms and other findings enumerated elsewhere, and, moreover, would offer no elucidation of the bladder picture.

The cystoscopies were done from four to eighteen days after the onset of the illness. In all of the thirteen patients whose bladders were examined, practically the same conditions were found: multiple small hemorrhages into the bladder mucosa without ulceration. There were from two to over twenty in each case, and, when numerous, they appeared to be somewhat grouped. They varied in size from minute punctiform spots to areas about 1 cm. in diameter, and were irregular in shape, often like a broad flame. They were usually situated definitely along the course of visible blood vessels, and were more common on the posterior wall and the posterior parts of the lateral walls of the bladder; twice they were present on the anterior wall, but associated with more numerous ones posteriorly. In four cases the trigon was involved, chiefly the proximal part, but not particularly the neighborhood of the ureteral openings. In every instance the ureteral orifices were normal. The bladder mucosa was normal (except for the hemorrhagic areas) in all but two cases, in which general engorgement of the blood was found.

Latterly five patients have been reexamined by cystoscopy. In none were we able to say that a new crop of hemorrhages had appeared. In four no sign of the old hemorrhages could be found, thirty, twenty-one, twenty and eight days after the first cystoscopy. In the last of these four cases, the original observation was "fifteen to twenty *minute* hemorrhages." In the fifth instance referred to there were numerous moderate sized lesions, some of which were still recognizable twelve days later, though of a brownish rather than a red color, and with less distinct borders.

Examination of the urethra by endoscopy should be made, and we hope to include this in the future studies.

Althought it is relatively easy to detect slight bleeding from the bladder wall or a tumor, with a good cystoscope used in a water medium, we have seen no bleeding from the bladder mucosa in any case. Moreover, it is not uncommon to find red blood cells in the urine of these patients after the bladder has cleared up. In some cases we have actually seen blood coming from the ureters, and we feel strongly that the upper urinary tract is the source of most of the blood found in the urine in the cases under discussion. Also, in view of the fact that the bladder evidences clear up rather rapidly, that recurrent hemorrhages into the bladder have thus far not been found, and that at present we are dependent on these cystoscopic signs for a diagnosis, it seems quite possible that the pathologic condition we are describing is more common than our figures show.

In two cases there was tenderness in one or both renal regions, but in no instance were the kidneys definitely felt. The external genitalia were uniformly normal. The prostate and seminal vesicles showed evidence of chronic inflammation on rectal palpation in only one case of the ten thus examined, and this man denied gonorrhea, and had not a trace of pus in the urine at the time of examination.

Pathologic Report.—We were able, by means of a small punch, to obtain specimens from the hemorrhagic spots in three cases. On section, these showed no typical lesions. The mucosa was entirely normal and unbroken. The submucosa showed a profuse and somewhat patchy infiltration of well preserved red blood cells, but no leukocytic infiltration, and nothing suggesting an inflammatory lesion. The blood vessels were somewhat engorged. In one specimen, small nodular accumulations of degenerating connective tissue cells and wandering cells were found in the vicinity of the small arterioles. No organisms could be demonstrated by Gram, Giemsa or Wright stain.

Two cases have thus far been omitted from the discussion. Although these patients ran entirely different courses from all the others, and gave evidences of hemorrhages elsewhere than in the urinary tract, it is impossible to leave them out entirely because they presented typical noninflammatory bladder hemorrhages, the only distinctive feature of the condition we are describing. One died with a general hemorrhagic condition, but at the onset of his illness the bleeding was confined entirely to the urinary tract. The other, after a six weeks' illness resembling trench fever, developed almost simultaneously cerebral symptoms and hematuria. The neurologic consultant thought the former could be explained only by multiple small cerebral hemorrhages. The typical bladder picture was found at cystoscopy, and the urine contained both blood and casts. The subsequent course, including urinary symptoms, was similar to that seen in other cases of this group. It may be that we are dealing with a hemorrhagic disease which usually reveals itself only in the urinary tract, but, in severe cases, also affects other organs.

COMMENT

The consistent presence of casts in the urine, and the reduction of the phenolsulphonephthalein excretion seem to be sufficient evidence to justify us in saying that these patients have a renal lesion. On the other hand, they differ in very essential respects from ordinary cases of acute nephritis. The common symptoms of edema and dyspnea are almost entirely lacking, as are uremic manifestations. Moreover, although we have examined by cystoscopy eighteen patients who had typical nephritis and hematuria, none have shown bladder hemorrhages, the most striking feature in our cases.

Sir John Rose Bradford[1] in 1916 suggested the presence of a distinct hemorrhagic nephritis. We quote from his article:

> In some instances, especially if the case is seen early, the urine may contain a large quantity of blood, so as to be obviously red to the eye. . . . Such cases present a rather different clinical picture to the general run of cases in that with them dropsy is neither so frequent, nor when present, so marked a feature of the case. Further, these hemorrhagic cases more frequently have pyrexia and resemble much more closely in their course infective nephritis dependent upon some microbic invasion. . . . In a few instances the hematuria and pyrexia have been intermittent and recurrent, producing a clinical picture closely resembling that seen in renal embolism; but these patients have not been suffering from any condition liable to cause embolism. . . . These cases, however, are few in number, and are quite different from the ordinary form of nephritis . . . where dropsy is really the dominant physical sign.

Dunn and McNee[2] have also called attention to a similar group of cases in their clinical analysis, but make no such distinction in the pathologic study.

The cystoscopic picture is entirely different from that seen in acute cystitis, where hemorrhages may occur but are associated with other signs of inflammation. Hemorrhagic spots removed from such bladders as controls presented an intense leukocytic infiltration, edema and tissue degeneration about the hemorrhages.

The bladder hemorrhages can not at present be distinguished from any other purpuric lesions, but a purpura of such frequent occurrence, which is apparently limited, in at least a large proportion of cases, to the urinary tract, is in itself worthy of note. Scurvy seems highly improbable.

It is possible that we may be dealing with a type of anicteric spirochetosis. A few microscopic examinations of catheterized urine sediments stained by the Fontana and India ink methods have been negative.[3] Of course, the evidence that we are dealing with a clinical entity is not complete, but the frequent occurrence of such a distinctive syndrome makes it seem probable.

We are continuing and enlarging the work, and hope that we shall be able to present detailed results with complete protocols at an early date.

PARAFFIN PAPER AS A SURGICAL DRESSING

CHARLES M. HARPSTER, Ph.G., M.D.
TOLEDO, OHIO

On account of the small supply and high cost of gauze, paraffin tissue paper will be found an excellent dressing for burns or any other condition in which a nonadherent dressing is desirable. It is far superior to the paraffin dressing of burns by the spray method, is much more easily and rapidly applied, results in more rapid healing of the burned surface, and is more easily removed.

In the first stage of burns, when there is great pain, the various ointments now in use can be applied directly to the paraffin paper and this applied to the burned area after all vesicles have been opened. It has the advantage of excluding the air, which relieves the pain of the burns, and it is readily removed at the time of redressing, leaving the developing granulations unaltered.

The first dressing, of pure petrolatum on paraffin paper, is applied directly to the burn, and over this a layer of cotton and the usual bandage. As the paper is impervious to moisture, the serum that seeps from the injury runs away from the raw surface, and is absorbed by the outer dressings beyond the injury. There is no sticking to the burn or other wounds, when the dressings are removed. Experience has proved that dressings once in two or three days are sufficient in most cases. Certain cases, however, may require more frequent dressings.

Paper bandages, which are now being universally used, perhaps more through necessity than choice, have been found to work well in certain dry dressings. But the thought arose, what a great saving could be accomplished if they could be used on moist dressings or dressings in which there is considerable oozing or drainage. Here again, the paraffin paper can be utilized as a barrier between the moist dressings and the paper bandage. It has the desired effect of keeping the moisture inside the dressing, and prevents the paper bandage from becoming wet and tearing easily.

The paraffin paper can be secured at almost any store where groceries are sold. An attempt is being made to have some dressing manufacturers put it up in sterile packages for general surgical use.

The advantages of the paper were accidentally discovered when a suitable dressing for a severe burn was needed at a patient's residence. The paper was ideal in this case. It has been employed in numerous other instances, and I have mentioned only a small number of its uses. It can take the place of oil silk or rubber tissue, in which case a double sheet is desirable, or, as I hope to secure soon, a heavier coated paper.

301 Wedgewood Building.

---

[3] More recently, injection of catheterized urine into guinea-pigs has proved negative in three cases.

SCIENCE AND FOOD PRODUCTION

The admonition of the United States Food Administration that we must save meat includes an implication to the dietetically thoughtful person that some other form of food rich in protein should be substituted for it in the diet. Among the products suggested for this purpose none offers greater promise of value than cheese. The attempt to encourage the use of cheese, in place of meat, is the more timely because, along with butter, it represents a way in which milk can be stored, so to speak, for future use. Furthermore, the administration officials have recently given assurance that large stocks of cheese are now on hand in this country and awaiting consumption. Until recently, at any rate, the United States could not be regarded as a cheese-eating nation in the same sense in which this might apply to European peoples. A census made in 1909 estimated the production of cheese for the United States at about 311,000,000 pounds. To this must be added a considerable importation, so that the cheese consumption was about 3½ or 4 pounds per person per year. This is a low figure in comparison with the amounts of meat and butter consumed, thus suggesting that there is room for considerable increase in the use of cheese.

One obstacle to the wider dietary employment of cheese in the United States at present lies in the fact that many types of this food have traditionally been imported; and until comparatively recent times it has been firmly believed—as still assumed by the majority of cheese lovers—that most of the many favorite brands cannot be produced elsewhere than at the original place of manufacture. The principal importations have been of Parmesan and Gorgonzola cheese from Italy; Emmenthal cheese from Switzerland; Roquefort, Camembert and Brie from France, and Edam cheese from Holland. These, however, by no means exhaust the list, particularly of the varieties which the epicure frequently has adopted.

Precisely as we are rapidly learning that the "made in Germany" brands of drugs and chemicals and diverse other essential items can be successfully replaced by home-made products, it is becoming evident that the quality of cheeses is not so much a question of countries and climes as of micro-organisms and science. When our dairy mycologists began to direct their attention to the changes that milk undergoes during fermentation and the ripening of cheese, it early became apparent that the nature of the product could be controlled and modified by the application of scientific methods. About three quarters of the cheese used at present in the United States is of the Cheddar type, often spoken of as American cheese. But cheeses of the Brie, Camembert, Neufchâtel, Swiss and Limburger types are also being successfully manufactured here, particularly in the great milk producing states of New York and Wisconsin.

The hard cheeses, such as the American Cheddar and the Swiss types, depend on a suitable bacterial flora for their normal development. In the softer cheeses, molds play an important part in the ripening. In these types also a rapid development of lactic acid bacteria is necessary to bring about the proper physical condition of the curd in the various stages of manufacture. Dr. Thom of the Bureau of Animal Industry, the foremost expert in this field of research, has shown that a specific mold, which he has termed *Penicillium roqueforti*, is concerned in the ripening of Roquefort, as well as of Gorgonzola and Stilton cheeses, and is responsible in large measure for their peculiar flavor.[1]

The problems of Roquefort cheese are illustrative of what our men—and women—of science are being called on to solve. This food product, which has been produced in southeastern France for at least two centuries, is a hard rennet cheese made from the milk of sheep. The imitations of it have been prepared from cow's milk, so that questions of identity of procedures and product have naturally become pertinent. In a recent investigation by Evans[2] in the Dairy Division of the Bureau of Animal Industry, it has been shown that the micro-organisms essential for the manufacture and ripening of Roquefort cheese are *Streptococcus lacticus* and *Penicillium roqueforti*. *Streptococcus lacticus* decomposes the lactose during the manufacture of the cheese, and thus produces the lactic acid necessary for the cheese making. These organisms disappear from the cheese after two or three weeks, being killed by the high concentration of sodium chlorid. The remaining flora of Roquefort cheese consists of cheese streptococci and *Bacterium bulgaricum*, organisms that are found in all kinds of ripening cheese. These organisms do not have any significant part to play in the ripening of Roquefort cheese. All experimental cheeses of this variety were made from cow's milk, but there was no evidence of any essential variation from the imported product. Such experiments in the control of complex biologic reactions and the reproduction of recognized desirable food products under new conditions of manufacture are timely and commendable. They initiate new possibilities and they attest the universality of science. Recently many persons have begun to look on science as an agent of subjugation; but it is certain to be far more potent as a force for the emancipation of mankind.

MODERN VIEWS OF HAY-FEVER AND ASTHMA

Recent work on hay-fever, asthma, eczema, urticaria and angioneurotic edema is being rewarded with interesting results. It has been noted that these various diseases are frequently associated in one family and occasionally even in one individual. Formerly, hay-fever was regarded as due to "a predisposing—perhaps neurotic—idiosyncrasy, a resulting hyperesthesia" and "an exciting agent"—pollen in true hay-fever, unfavorable atmospheric conditions in so-called pseudohay-fever. Now, however, not only has stress been placed on the resemblance of the symptoms in hay-fever, asthma and allied conditions to some of those of active anaphylaxis (by Wolff-Eisner, Meltzer and others) but, as Koessler[1] says, it has been proved by experiment that hay-fever is a disease due to pollen protein sensitization. It has been shown also that asthma in certain cases may be precipitated by inhalation, by subcutaneous injection or by ingestion of the foreign protein to which the individual is sensitized, as in horse asthma or in patients who develop from their hay-fever true paroxysms of asthma.[2] In similar manner, certain forms at least of eczema, urticaria and angioneurotic edema have been determined to be forms of protein sensitization, and new methods of diagnosis and treatment are being worked out.[3] With this new point of view, the "predisposition" of former times is now "sensitization" or "allergy," and the exciting agent is the specific foreign protein, as pollens in hay-fever, and pollens, animal emanations, food or bacterial proteins in asthma, eczema, urticaria and angioneurotic edema.

The offending protein may be detected by cutaneous and ophthalmic tests with extracts of the suspected proteins. The tests are based on the fact that the cells may react to the protein involved when applied directly. While the significance of such tests has not yet been worked out completely, the results indicate that the diseases are indeed examples of allergy. This is true of hay-fever quite generally, of asthma also but with exceptions, and of certain forms of eczema, urticaria and angioneurotic edema, as found with increasing frequency. These allergic diseases appear to carry a definite inheritance factor, a positive family history being found in something like 50 per cent. of susceptible persons, as against 14 per cent. of normal persons. It has been claimed that the capacity for sensitization is transmitted nonspecifically as a mendelian dominant, specificity being acquired usually in a manner as yet ill understood through inhalation, ingestion or intradermal reception of foreign protein.

In a recent report on so-called horse asthma as well as asthma from other forms of sensitization, de Besche[4] describes the case of a physician that illustrates not only early onset of asthma and its association with hay-fever in the same person as well as in other members of the family, but also the induction of typical anaphylactic shock on the injection of antidiphtheria serum, followed for a time by an apparently complete desensitization. In this case as well as in others, specific eye and skin reactions were obtained with horse serum, the eye reaction being obtained by simply touching the conjunctiva with the finger, which had just touched a horse. When the patient's serum was injected into a guinea-pig, horse serum being injected a few hours later, anaphylactic shock resulted. In one case death—passive anaphylaxis—occurred. It is of interest to note that in the case of the physician, exposure to emanations from horses, injection of horse serum, and the ingestion of sausage containing horse meat all caused asthmatic attacks; this patient was sensitive also to rabbit and guinea-pig emanations as well as to rabbit serum. Other cases of asthma described are in many ways similar; but, as commonly observed, with variation in the age when the nature of the trouble was recognized as well as in the course and in the symptoms. In one patient, acute gastro-intestinal symptoms developed, corresponding to the so-called anaphylactic gastro-enteritis. It appears that not all persons subject to horse asthma are sensitive to horse serum, and that consequently the danger of injecting antitoxic serum is less than might seem to be the case at first glance; but the necessity of careful tests of all asthmatics before injecting serum for therapeutic purposes, now generally recognized, remains as obvious as ever. Among other instances of sensitiveness described by de Besche is one of hay-fever-like manifestations associated with pronounced acute gastro-intestinal disturbances caused by flowers, more particularly roses; whenever exposed for fifteen or twenty minutes to the odors of roses, this patient, a man, had colic and diarrhea at the same time as sneezing and running of the eyes. In some of the instances recorded, the sensitiveness appeared to increase with time. As stated, we do not understand fully how this abnormal sensitiveness develops, whether it is inborn or acquired. Bearing on this question, a case recorded by Walker[5] is of special interest: a woman, aged 20, who had not had asthma before, was injected with horse serum without any immediate ill effects; but two weeks later she began to have asthmatic attacks whenever in close contact with horses, and alcoholic extracts of horse dandruff gave a skin reaction. Here we have a definite instance of acquired sensitiveness.

[4] De Besche, Arent: Hypersensitiveness and Asthma, Especially in Relation to Emanations from Horses, Jour. Infect. Dis., 1918, **22**, p. 594.

Treatment of these allergic diseases includes protective as well as curative measures. The protective treatment aims to exclude the offending protein from reaching the sensitive patient. It is illustrated well in the case of hay-fever, not only by the migration of hay-fever victims to regions that are free from the pollens concerned, but also by the elaborate campaign against hay-fever waged by the American Hay-Fever Prevention Association,[6] aided by various governmental agencies. Some large cities now limit by weed-cutting ordinances pollination of the grasses and weeds causing hay-fever, and New Orleans is said to have decreased by these means the vernal type of hay-fever by more than 50 per cent in one season. The varieties and distribution of plants bearing hay-fever pollen are being determined, and undoubtedly preventive work of this kind if continued and extended will result in great reduction of the suffering from hay-fever. Persons subject to horse asthma are especially liable to attacks in places where horses abound, and de Besche mentions instances of complete relief from all symptoms when such persons leave the city and go to sea.

At present, the only form of curative treatment that offers any promise of help is based on the principle of desensitization (antianaphylaxis, anergy), injections being given of the particular proteins to which the patient in question is abnormally sensitive, the dose being selected with a view to avoiding severe reactions, as determined by ophthalmic or cutaneous tests. The effects so far obtainable are not marked, and repeated injections are necessary. In hay-fever the treatment with extracts of pollen is begun several weeks before the usual onset, and continued at intervals during the season. The results in hay-fever seem to be encouraging; the drawbacks are lack of permanence in result and difficulties connected with dosage. In other forms of sensitiveness, the specific treatment is being made the subject of careful investigation.[3]

DEHYDRATED VEGETABLES

The conservation of certain types of foods, notably fruits and vegetables, by desiccation has been brought into public prominence by the propaganda of the United States Food Administration and other agencies for inculcating food-saving. The preservation feature of this program is quite clearly understood by most persons who have given attention to the subject. Less well appreciated are some of the other features of the dehydration plan, particularly the actual change in the composition of the products with respect to their water content. The removal of the water not only yields a desiccated product that is not very likely to be lost by spoilage and decay, but also does away with the great bulk of the material so that the possibility of economy in transportation is greatly enhanced. Saving in tonnage and cargo space is at times an item quite as important as the other advantage afforded by desiccated products, namely, availability in seasons when fresh supplies are not readily obtainable.

In commenting on dehydrated vegetables, during a recent address delivered before the College of Physicians in Philadelphia, Major Murlin[1] of the Food Division of the Surgeon-General's Office called attention to some of the advantages which such foods offer in war time. He reported that the quartermaster's department of the Army has begun to place orders for dehydrated vegetables such as potatoes, onions and carrots for the use of General Pershing's army. As yet the tonnage contracted for is not large, but in all probability in the near future dehydrated vegetables will become a staple in our army rations, as they have already become in the ration of the British army. Thousands of pounds of dehydrated vegetables are being prepared in Canada, some also in the United States, for the British army. By simply soaking in water and boiling in the same water, these vegetables are brought back to the condition of fresh vegetables so perfectly that very often they cannot be distinguished from the fresh vegetables themselves. According to Murlin, another advantage of such products is the very high saving of time in the company kitchen. Dehydrated vegetables put up in packages are ready for the kettle; this saves the work of one or two men a day.

Elsewhere in this issue Givens[2] has presented statistics that elucidate some of the actual consequences of desiccation. A series of analyses of dried vegetables, conducted at the Sheffield Laboratory of Physiological Chemistry in Yale University, show that the quantity of water lost by such foods as spinach, lettuce, carrots, potatoes and cabbage may range from 70 to 97 per cent. Thus an entire barrel of spinach becomes concentrated into a package weighing at most a few pounds. Incidentally, it is noted that some of the green edible parts contain not insignificant quantities of calcium, an essential element which is ordinarily derived most readily in abundance from milk and milk products. For example, Swiss chard and spinach may contain more than 1.25 per cent. of calcium: cabbage and lettuce may furnish more than 0.5 per cent. As the requirement of lime for an adult man has been placed at somewhat less than 0.5 gm. a day, the small contributions from liberal quantities of such green vegetables may not be negligible, provided they are physiologically available in these products. This remains for the most part to be ascertained by actual utilization experiments.

Current Comment

VOCATIONAL REHABILITATION OF THE DISABLED SOLDIER

THE JOURNAL has frequently stated that the most important future work connected with the war is the rehabilitation and placement in a vocation of the disabled. It has stated that this work properly should come under the supervision and direction of the Surgeon-General of the Army or the Navy, as the case might be. Recently Senator Smith of Georgia introduced a bill which looked to the transference of some of this work to the Federal Board for Vocational Education. According to the original bill, this work, while theoretically under the supervision of the Surgeon-General, would in reality have been under the supervision of this Federal Board. This, of course, would have been a serious handicap to good work. As the bill passed the Senate, it was so modified as to make the measure a fairly satisfactory one. It must be recognized that an entire program which shall deal with the disabled soldier in an effective way must involve his medical and surgical treatment, whatever reeducation may be necessary, and his final placement or aftercare. While the Surgeon-General of the Army had facilities to do all of this work, and, in fact, had worked out a program, other federal agencies also were prepared to do part of the work supplementary to the medical and surgical treatment. The bill leaves the soldier, or sailor, under the entire authority of the War Department or Navy Department—that is, in the Medical Department of the Army or Navy—until discharged from the service. The Surgeon-General may deal with the soldier in an attempt to cure him, or as nearly so as the man's disabilities permit, without outside interference. The bill provides that no "vocational teaching shall be carried on in any of the hospitals until the medical authorities certify that the condition of the patient is such as to justify such teaching"; also that "the plan may be established between the War and the Navy Department and the Federal Board for vocational education whereby these departments will act in an advisory capacity with the board in the care of the health of the soldier after his discharge." Necessarily, if the program as outlined by the bill is to be carried out in a satisfactory manner, there must be hearty cooperation between the Federal Board and the Surgeon-Generals of the Army and of the Navy. There is no reason to suppose that this cooperation will not be entered into fully by these different interests, and to the ultimate, best advantage of the disabled soldier.

DOMINATION OF THE MEDICAL PROFESSION BY COMMERCIAL INTERESTS

Last week THE JOURNAL published a letter received by a physician in Milwaukee from a firm of lawyers representing the Farbwerke-Hoechst Company. In this communication the physician was threatened with suit if he published further unfavorable reports regarding that firm's preparation. Quoting from the attorneys' letter:

> "Mr. Metz directs us to inform you that the publication of this article and the statements therein were seriously damaging to the Farbwerke-Hoechst Company, and directs us to say further to you that he and the corporation will hold you personally responsible for any repetition, oral or written, of the same or of similar statements to the same effect."

We were under the impression that the time had passed when a proprietary medicine manufacturer would presume to threaten a physician for making an honest report of his results with any therapeutic agent. Such condition did exist once, before the Council on Pharmacy and Chemistry undertook its work. Now comes Mr. Metz to revive this relic of an historic but infamous period in the history of American proprietary medicine manufacturing. Even Mr. Vanderbilt regretted that he ever said "The public be d——." One of the elementary principles in the practice of medicine is that the individual physician shall let others know his results, whether good or bad, in any line of treatment. It is by such interchange of knowledge and experience that progress in medicine is possible. Yet Mr. Metz would interfere with the diffusion of such knowledge and experience when it applies to proprietary medicines. His legal threat against Dr. Sargent is "terrorism" applied to the medical profession.

DRUGLESS HEALING INCLUDED IN THE TERM "PRACTICE OF MEDICINE"

A decision handed down a few months ago[1] by the Supreme Court of Illinois will help to do away with the confusion resulting from the licensure of cult practitioners. Under the claim that they were "not practicing medicine," osteopaths, chiropractors, Eddyites, naprapaths, physcultopaths, neuropaths and other healers are claiming or have secured the legal right to practice with lower educational qualifications than are required of physicians. But their claims are no longer valid—at least in Illinois. This decision states that the term "medicine" is not limited to substances supposed to possess remedial properties, but also means "the healing art"—the science of preserving health and treating diseases, no matter whether medicinal substances are used or not. But the decision does not end there. It adds emphasis to the foregoing by the statement that any one engaged in the treatment of diseases for the purpose of curing them is a physician. The corollary is also true, therefore, that all who are practicing the healing art by whatever method should be required by law to possess the same educational qualifications. Incidentally, this decision specifies that any physician, regardless of the method of treatment followed, has the right to sign death certificates. This emphasizes all the more the necessity of adequate training for any one who has this authority. The objections that have been raised to the signing of death certificates by followers of the various cults has not been because of the particular form of treatment they emphasize, but because of their lack of a fundamental training in the essentials of medicine. Enforce the same qualifications alike for all who are legally authorized to treat the sick — the same as is done in practically every other country — and there will be no logical reason for restricting the practice of any one engaged in the healing art who, in the light of this decision, is a physician and is engaged in the practice of medicine.

NURSES NEEDED BY THE RED CROSS

On June 10 the American Red Cross will initiate a campaign to secure 25,000 nurses for the United States Army and Navy. It should be emphasized that the nurses needed are those from regularly established training schools, who are registered to practice nursing — not the voluntary nurses' aides nor untrained or so-called "practical" nurses. There is already a severe strain on the supply of registered nurses. This will be an additional strain. For this country to supply 25,000 in addition to those already in the military service — between 10,000 and 12,000 — means that physicians and patients will have to get along with fewer nurses. The physician who assigns a trained nurse to a maternity case must now realize that his patient will be able to have this nurse for only a part of the usual time — perhaps only for the day of delivery and three or four days following, and must substitute untrained nursing assistance, if even this is necessary. In ordinary cases of illness the "practical" nurse is often as satisfactory as the thoroughly trained, registered nurse. Incidentally, this forced economy in the use of nurses may not, after all, be an unmixed evil. Many of us have become so accustomed to this trained assistance that we seem to feel that we cannot get along with any other kind. It is an illustration of the old saying that what was a luxury yesterday is a necessity today. We have come to regard a trained nurse as a necessity in illness, in which, twenty-five years ago, even such a luxury as a "practical" nurse was undreamed of. But this is looking at the nurse solely in her narrow field. In recent years she has developed into more than the doctor's assistant; she has become an important, and in some respects a necessary, aid in carrying on the social work that has developed during the last decade or two. It is as visiting nurses — among the poor, in our schools and in infant-welfare work — and as public health workers — it is here that this great demand on account of the war will be most felt, for here the demand for nurses had already become greater than the supply. Physicians should realize that they can do as much as, if not more than, any other class in encouraging young women of proper training, who seem fitted temperamentally and otherwise for this work, to undertake the training courses now so readily available. There are many who have some ambition in this regard and who, with a little encouragement, would enter on this training. In any event, for the time being it must be borne in mind that nurses are one of the great needs in winning the war, and that it is our duty as physicians to aid in supplying this need.

GASTRIC SECRETION IN FEVERS

Ordinary clinical observation is frequently sufficient to afford unmistakable evidence of defective alimentation in the course of febrile disease. Naturally, the stomach and its functions have received a great deal of attention because they are relatively easy to investigate. Observers agree that there are a diminished gastric secretion and a lowered acidity in fevers; but whether the factors involved in this outcome are partly or entirely of a nervous character, as some persons have believed, or whether some chemical agency in the work of the gastric glands is concerned has never been established. We may thus still ask, as one group of investigators have formulated the question, Does the fever or temperature elevation complex abolish the psychic factor, impair the function of the hormones that provoke the secretion, or depress the gastric cells directly? From recent experiments by Meyer, Cohen and Carlson[1] at the Hull Physiological Laboratory of the University of Chicago, an answer to such queries now seems possible. The experiments indicate, so far as studies on suitable animals are available to give an answer, that during fever gastric secretion is diminished in volume and in total and free acid. The percentage of chlorids is constant or only slightly reduced, and pepsin is relatively increased. The secretion is ropy and mucous in character. The discovery that gastrin, the specific hormone that promotes gastric secretion, can bring its effect about after subcutaneous injection, and under conditions in which psychic factors cannot come into play,[2] makes it possible to distinguish between such factors and chemical effects on the stomach in febrile conditions. Gastrin, which is now believed to exert a direct action on the cells of the gastric glands, will not induce a secretion of gastric juice during typical fever. Furthermore, it will not act during a condition of elevation of temperature brought about by excessive external heat. The fact that the latter, when sufficient to induce a temperature elevation of from 2 to 4 F., will cause the same changes in gastric juice as are produced by fever, points to the heat itself as the most prominent causal agency in the disorders of secretion induced by fever. The theory of the Chicago physiologists is that the most important feature in the alteration is a depression of the gland cells. These cell changes, they believe, are transitory in character, and are probably in the nature of a cloudy swelling. The further suggestion is made that, during fever, toxins are perhaps elaborated having a direct depressor action on the cells of the stomach so that they fail to react to the secretory nerve impulses and to the secretagogues. If this is true, a comparable inhibitory or depressive effect on other glandular cells may likewise be expected to occur and thus still further aggravate the alimentary difficulties of the febrile patient.

GESTATION AND LACTATION

It has been believed among the laity as well as by a few physicians that pregnancy and lactation are incompatible and that "the pregnant woman must wean her child because of the marked influence which pregnancy exerts on the composition of milk." If we seek for the origin and ask regarding the validity of this assumption, dependable facts are not easy to find. There are reports to the effect that children nursing pregnant mothers tend to exhibit symptoms of indigestion and impaired nutrition. These phenomena are attributed to the scanty flow of milk under the conditions stated and to a possible alteration in its quantitative make-up. In the case of cows, the problem here presented ought to be open to solution from an experimental standpoint, because nearly all of these dairy animals are bred at some stage of their lactation period. The studies of Palmer and Eckles[1] of the Department of Dairy Husbandry at the University of Missouri have led them to the conclusion that gestation does not exert any direct effect on the composition and properties of cow's milk, but that gestation may affect the composition indirectly by hastening the close of lactation, which is the important factor involved in the changes in the composition of milk as lactation advances. An elaborate series of analyses of the milk of two lactating women indicates, further, that under normal conditions gestation exerts no influence on the composition of mother's milk, but that it may greatly hasten the close of lactation with the changes in the composition of the milk which accompanies it if lactation is sufficiently advanced when the period of gestation begins. Despite the fact that disturbances in the health of the children nursed by these pregnant mothers were never noted, Palmer and Eckles frankly admit, in view of the limited data still available, that the whole question is worthy of more extended study, particularly with regard to the disturbances in the health of the child which have been mentioned as accompanying pregnancy in the case of the mother. They add that the variations in the composition of human milk, the factors that contribute to these variations, and the relation of these variations to the health and nutrition of the child have not received the attention they deserve. Similar information in regard to cow's milk is much more extensive at present. Many opinions regarding the extent of the variations to which the composition of cow's milk is subject, which were formerly held by many persons, have been disproved, but are still regarded as being true for human milk. No doubt, Palmer and Eckles conclude, many of these opinions are equally unfounded for human milk; but the experimental data are not available to disprove them.

IS SALICYLIC ACID EXCRETED AS SALICYLURIC ACID?

When benzoic acid is introduced into the organism it is excreted in combination with glycocoll as hippuric acid (benzoyl glycocoll). This well established fact has long been cited as an evidence of the synthetic capacities of the body, and further as an illustration of its detoxicating devices; for, by conversion to hippuric acid, benzoic acid becomes comparatively inert to living tissues. Many grams of benzoates — more than an ounce — can easily be converted in this way. An analogous reaction has also been believed to occur when the closely related hydroxybenzoic acid, salicylic acid, finds its way into the circulation. The salicyluric acid (salicyl-glycocoll) is said to occur in urine to the extent of about 80 per cent. of excreted salicyl in man after the administration of salicylates. Hanzlik,[1] of the Pharmacologic Laboratory of Western Reserve University, has found, however, that the methods which have been used heretofore for isolating what was supposed to be salicyluric acid are inadequate. Even when applied to salicyl urines they do not yield any notable quantity of a pure product of the character expected. From this it accordingly appears improbable, as Hanzlik argues, that salicylates are conjugated with glycocoll and converted into salicyluric acid in the human organism. The products hitherto interpreted as salicyluric acid have presumably been more or less impure salicylic acid that had been imperfectly separated in the process of isolation. These few conclusions do something more than teach us that the salicylates are excreted, in good part at least, unchanged. They warn against the folly of transmitting from one edition of a textbook to its successors, through an entire generation, reputed discoveries based on slender evidence.

Slicing the Patella.—H. Spitzy recommends sawing the patella through into halves, nearly parallel to the surface, to obtain ample access to the joint. By this means the ligament attached to the sawed off upper half of the patella is left undisturbed, while the quadriceps tendon attached to the lower half is also left unmolested, and yet the two halves can be drawn apart, leaving the joint amply exposed below. When the operation is completed, the halves of the patella are superposed and sutured together with a circular suture embracing both capsule and periosteum. The *Correspondenz-Blatt* adds in its summary from the original article in the *Münchener medizinische Wochenschrift*, No. 35, 1917, that Spitzy has applied this method in two cases with most excellent results, and has also used the same technic for the elbow, sawing off a slanting slice of the olecranon without molesting the triceps tendon.

Association News

THE CHICAGO SESSION

PROGRAM OF MEETINGS

The annual session of the American Medical Association convenes Monday, June 10, with the opening meeting of the House of Delegates at 10 a. m. at the home of the Association at 535 North Dearborn Street. Meetings of the House of Delegates will continue throughout Monday and Tuesday. The General Meeting which constitutes the opening exercises of the Scientific Assembly will be held at 8:15 p. m., Tuesday, June 11. The various sections of the Scientific Assembly will meet Wednesday, June 12, at 9 a. m., continuing throughout Wednesday. Practically all of the sections will combine on Thursday in the meetings of the Section on Miscellaneous Topics in the Auditorium Theater, beginning at 9 a. m. This meeting will be devoted to consideration of reconstruction and rehabilitation of the disabled soldiers. The Scientific Assembly will continue throughout Friday for most of the sections. On Wednesday evening, June 12, at 8:30, the military medical meeting takes place in the Medinah Temple. At this meeting the speakers will be representatives of the Medical Corps of the allied nations. On Thursday evening at 8:30 a patriotic meeting will be held in the Auditorium Theater. There will also be meetings devoted to consideration of the relations of physicians to the selective service to be held Thursday afternoon and Friday morning at the Studebaker Theater. The program of these meetings was published last week.

The registration, scientific and commercial exhibits will be open from 8:30 a. m. until 5:30 p. m., Monday, Tuesday, Wednesday and Thursday, June 10 to 13; and from 8:30 a. m. until 12 noon on Friday, June 14.

THE BRITISH DELEGATES TO THE ANNUAL SESSION

Sir James Mackenzie, Sir Arbuthnot Lane and Col. Herbert Bruce, delegates from the British Medical Association to the meeting of the American Medical Association, arrived in New York City on May 31. They were met and welcomed by Dr. Wendell C. Phillips, member of the Board of Trustees, and by Dr. Alexander Lambert, chairman of the Judicial Council in behalf of the American Medical Association. On June 2 they left for Washington, D. C., where they remained until June 4 when they departed for Cincinnati to attend the annual session of the American Surgical Association. They will arrive in Chicago, Sunday, June 9, for the annual session of the American Medical Association from June 10 to 14, and will be at the Blackstone Hotel.

MILITARY MEDICAL HEADQUARTERS

Room L on the mezzanine floor of the Hotel Sherman, adjoining the Scientific Exhibit, has been reserved as headquarters of the Medical Department of the Army. A representative from the Medical Department of the Army will be at this room every day, commencing Tuesday, prepared to give information concerning the service. Application blanks, circulars of information, etc., can be had there; and arrangements can be made for the examination of those who desire to apply for commission in the Medical Reserve Corps.

LADIES' ENTERTAINMENT

In addition to the announcements already made, arrangements have been made for a trip to the Great Lakes Training Station on Wednesday afternoon. The occasion will be the dedication of the new Red Cross building at the training station. The train will leave the Northwestern Station at 1:30. Members of the Women's Committee will be at this station to accompany the visiting ladies to the Great Lakes Training Station, where they will be guests of the training station.

MEETINGS DURING THE ANNUAL SESSION

Chicago Pediatric and Infant Welfare Society

A joint meeting of the Chicago Pediatric and Infant Welfare Societies will be held June 10 at the City Club of Chicago, 315 Plymouth Court. Addresses will be given by Dr. William Palmer Lucas on "Child Welfare Work in France" and by Dr. Paul Armand DeLille on "The Infant Mortality Situation in France."

Chicago Ophthalmological Society Banquet

The Chicago Ophthalmological Society will give a banquet and entertainment in honor of the officers of the Section on Ophthalmology of the American Medical Association in the East Room of the Hotel La Salle, Chicago, at 6:30 o'clock, Tuesday evening, June 11. Tickets for the banquet may be procured from the secretary of the Chicago Ophthalmological Society, Dr. Alfred N. Murray.

Medical Mobilization and the War

An English Appreciation of American M. R. C. Officers

Colonel Furbush, of the Surgeon-General's Office, sends the following excerpts from a letter which he received from Lieut.-Gen. T. H. Goodwin, Director-General of the British Medical Service. The letter is dated May 8:

"This is only a short line as I am extremely busy. I would like to give you an extract from a letter which I have just had from G. H. Q. in France. It runs as follows:

> 'The casualties amongst Medical Officers during the week have been 23, of whom 3 were killed. 5 of the casualties were amongst Medical Officers of the U. S. A. attached to British battalions or field ambulances, 4 being "gas" casualties and one "missing" casualty. The work of these U. S. A. Medical Officers deserves special recognition. They have been invaluable and have worked under the most trying conditions and with great gallantry.'

"I thought you would like to know this, and I should be much obliged if you would show it to the Director-General. You are, of course, entirely at liberty to make it known in whatever way you wish, in fact, I should be glad if you would do so for I feel strongly how much we owe to your country, and I should like your people to know how well your Medical Officers are doing. . . ."

General—then Colonel—Goodwin, it will be remembered, was in this country for over a year, and a large number of our readers will have personal remembrance of him.

It is gratifying to read the message General Goodwin sends. It must be borne in mind that the letter from which General Goodwin sends the quotation was not written with the idea that it would be presented to American readers, but for "home consumption."

Moral Welfare of Military Establishments to Be Further Safeguarded
